Each group contained 50 women. In Group A 25 and in Group B 26 were primigravidae. The symptoms were recorded by independent antenatal officers who had no knowledge as to which patients were receiving the additional substances. All patients developing albuminuria, showing hypertension or suffering from excessive vomiting or oedema were admitted into the antenatal ward. Those suffering from insomnia or severe headaches were also advised to go into hospital.

RESULTS

The results obtained are shown in Tables I and II. The symptoms of the patients admitted for albuminuria and hypertension are not included, so that the heading symptoms refers to patients

This obstetric unit is affiliated to the British Postgraduate Medical School, Hammersmith, London.

suffering from "other symptoms" are shown in Table II, most patients complaining of more than one symptom.

COMMENT ON THE FINDINGS

Prof L. S. Pearson, of the department of statistics at University College, London, has been kind enough to study these figures and has expressed the opinion that the difference in incidence of "complications" between the two groups is very unlikely to have arisen by chance. It is therefore desirable to consider factors, other than the diet, which may have contributed to this difference.

Of the 100 patients, 76 were between twenty and thirty years of age. Of the primigravidae 4 (2 in each group) were under the age of twenty, each being nineteen years of age. The number of women over thirty was 20, including 2 primigravidae in each group. 9 of these were in Group A and 11 in Group B. It is thus evident that the ages of the women in the two groups were strictly comparable.

It has already been stated that no regard was paid to the previous obstetric histories of the multigravidae. There are arguments in favour of confining future experiments to primigravidae, but it would have been impossible to take previous obstetric histories into consideration unless all the confinements had taken place in comparable institutions. One woman in Group A, admitted for albuminuria and hypertension, had been twice previously confined—on both occasions in St. Mary Abbots Hospital. In her first pregnancy she had suffered from eclampsia and during her second pregnancy she was admitted for albuminuria and hypertension. As the result of treatment in the ward her urine became protein free and her blood pressure returned to normal limits before she was delivered of her third child. The previous obstetric

histories of many of the patients were unobtainable, but it is significant that the same difference in incidence of "complications" between the two groups is observed among the primigravidae as among the multigravidae.

All the patients in the experiment were observed equally often over approximately the same period of time. No woman was included who was not in the position to take the "protective substances" for sixteen weeks before delivery, and no one took them for more than twenty weeks. The social status of all the patients was, so far as could be judged, strictly similar. There was no room for variation in the "standards" adopted by the antenatal officers, for the criteria were well defined. If albumin was found in the urine a catheter specimen was subsequently obtained and tested. No patient was recorded as suffering from albuminuria unless albumin was detected in a catheter specimen. Similarly, no patient was admitted for hypertension unless, after rest, the systolic pressure equalled or exceeded 140 mm. Hg. A symptom, such as headache, was accepted only if it persisted and was severe. Moreover, I myself saw every patient who was admitted to the antenatal ward and confirmed the findings of the antenatal officers.

It therefore seems logical to assume that the difference in the incidence of "complications" between the two groups must, if not due to chance, be attributed to the substances given. This assumption is strengthened by the results of the dietetic treatment of these patients in the antenatal ward. The symptoms cleared up in every case. A slight degree of albuminuria, not exceeding 0.05 per cent, persisted in 3 of the 13 patients admitted for this condition, while the blood pressure returned to the normal in 13 of the 16 patients admitted for hypertension. These results strongly suggest that the other main factor in the prevention of the toxæmias of pregnancy is the vitamin B complex.

It is somewhat disappointing that, after waiting so long for the opportunity of conducting this experiment, the number of women included should be so small. This is due to the fact that only a small proportion of the patients booked sufficiently early and attended the hospital antenatal clinic throughout their pregnancies. These results, however, point in the same direction as those obtained by Mendenhall and Drake,¹ and are published in the hope that further experiments on a larger scale will be conducted elsewhere. There is no proof that all the patients in Group A took their capsules and tablets regularly, and it might be expedient to incorporate a trace of methylene blue in each tablet.

Experiments conducted on these lines would show to what degree, if any, the different protective substances are associated with toxæmic symptoms. It is my belief, for instance, that vitamin A is of more importance in preventing senile changes in the placenta, and consequent death of the fetus, than in preventing toxæmic symptoms. Then too, experiments conducted in different parts of the country might show that the degree of deficiency of any given protective substance varied from area to area. On the other hand, all the protective substances could be incorporated in a pill and a capsule and be distributed at a cost not greatly exceeding that of a daily pint of milk.

There is one further and still more important reason why such investigations should be under-

¹ Mendenhall A. M. and Drake J. C. (1934) *Amer. J. Obstet. Gynec.* 27: 890.

taken. Some authorities maintain that the great majority of the adult population suffers from some degree of malnutrition, while others deny that there is any evidence other than an incidence of secondary anaemia in favour of such a conclusion. Dietetic surveys indicate that the average intake of the protective substances is inadequate when calculated on a rat basis but the transference of results from the rat to man is not justified and it must be admitted that the optimum and minimum human requirements of these substances are not known. It is however universally accepted that pregnancy makes an increased demand on the maternal stores of the vitamins and minerals, and this is true of every experimental animal. If therefore neither the toxæmia of pregnancy nor intra uterine death of the foetus are to be attributed to dietetic deficiencies then it may be asserted that there is no evidence whatsoever that any significant section of the adult population suffers from malnutrition. Conversely

if the toxæmia of pregnancy are due to this cause then there is every justification for the assumption that similar symptoms and diseases, such as insomnia, headaches, cramps, pyælia, albuminuria, hypertension, skin rashes and jaundice occurring in the non-pregnant state, may likewise be due to dietetic deficiencies. It may with reason be concluded that the proof or disproof of the dietetic deficiency hypothesis of the toxæmia of pregnancy affords the only available experimental means of determining whether malnutrition other than iron deficiency is a significant cause of ill health and diminished vitality in the adult population of this country.

I have pleasure in thanking Sir Frederick Menzies, medical officer of the County of London for permission to carry out this experiment and to publish the results. I should also like to take this opportunity of thanking Miss F. R. Slendon, the maternity sister for so willingly undertaking the extra work necessitated by this investigation.

CLINICAL AND LABORATORY NOTES

INTUBATION OF THE MAXILLARY ANTRUM FOR ACUTE EMPYEMA

By N. ASHERSON, M.B. Lond., F.R.C.S. Eng.

ASSISTANT SURGEON TO THE CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.

PUNCTURE with subsequent lavage of the maxillary antrum through the inferior meatus is a common way of dealing with an acute empyema of the antrum for both diagnosis and therapeutic. Antral puncture is especially indicated when after a cold or influenza the antral infection gives rise (as it frequently does) to severe face ache, facial neuralgia or supra orbital neuralgia. This underlying acute sinusitis is a condition which is more frequently overlooked (except by rhinologists) than any other disease.

When the presence of an empyema of the antrum is confirmed by the lavage it may be necessary to repeat the puncture and lavage on subsequent occasions. Patients shrink from this repeated puncture under local anaesthesia and consequently I always (where possible) perform antral puncture under a short nitrous oxide and oxygen anaesthesia. The patient is permitted to regain complete consciousness before the lavage is commenced.

Antral drainage (antrostomy) is called for the case that fails to respond to repeated antral puncture and lavage. This operation is not devoid of complication of which the most frequent are otitis media and acute streptococcal meningitis.

METHOD

Repeated antral punctures and even an antrostomy can be avoided by the following procedure which I term intubation of the antrum.

The intubation cannula (see Figure) is short straight and of wide bore. The flange is perforated by a slot on each side to which a strong thread is applied. The cannula is of such a length that when it is inserted into the antrum the flange lies just outside the nose, flush

with the upper lip. It is retained in situ by strapping the threads to the cheeks.

Using this special retainable antrum cannula the antrum is punctured with the trocar and cannula through the inferior meatus. The trocar is withdrawn and the cannula left in situ. The antrum is perfused with saline. A loose pad of gauze is also strapped over the nose.

The patient is confined indoors or to bed, and every 3 hours the first day every 4 hours the next day and subsequently three times daily the antrum is irrigated about a pint of sterile tepid saline being used. The cannula is left in for up to a week, when it is withdrawn, cleaned, sterilised and reinserted.

Should the ostium of the maxillary antrum be blocked—as shown by an inability to perfuse the antrum—the cannula should be left in situ for 24 hours and the lavage again attempted. Sooner

or later this becomes possible as in Case 2.

ILLUSTRATIVE CASES

I originally devised intubation for use in the first of the following cases where a plastic operation on the cheek on the same side as the empyema of the antrum was contemplated. A pedicle graft from the abdomen had already been grafted on to the forearm preliminary to transplanting it on to the cheek to cover a scarred area left after the treatment of an extensive facial nevus.

CASE 1.—Acute empyema of antrum cured by intubation of the antrum.

A girl of 20 complained of a right nasal discharge with severe pain over the antrum due to an acute empyema of the antrum. An enormous amount of stinking pus was removed by antral lavage following the antral puncture. The cannula was left in situ and antral lavage was then performed every four hours during the day for two weeks, the cannula being changed every five days. For the first 10 days pus was irrigated from the antrum but within 3 weeks the infection cleared up completely.

The cannula is made to my design by Messrs. Mayer and Phelps, London.

Above The intubation trocar and cannula

Below The cannula alone (natural size)

It was necessary in this case (a) to get rid of the antral infection rapidly, in view of the imminent grafting of the pedicle flap from the arm to the face, (b) a Caldwell-Luc operation was not possible as encroaching on the plastic surgeon's field, (c) intra-nasal antrostomy would not have obviated the necessity for repeated antral lavage apart from carrying the risk of an acute otitis media or streptococcal tonsillitis.

CASE 2—Acute exacerbation of a chronic antral infection treated by intubation of the antrum.

A man of 42 developed an acute infection of the left antrum followed by an acute otitis media. Transillumination and radiography revealed an opaque antrum. On puncture of the antrum no fluid or air could be perfused owing to the ostium being blocked. The cannula was left in situ for 24 hours after which antral lavage was easily accomplished, the ostium having become patent with the relief of the tension in the antrum through the intubation tube.

SUMMARY

Intubation has the advantage of giving that continued antrum drainage which is otherwise only obtainable by an operation, avoids any complications of the latter, does not incapacitate the patient to any extent, and its application in suitable cases will prevent the condition from becoming chronic.

HÆMOGLOBINURIA FOLLOWING EXERTION

By W. H. W. ATTLEE, M.D. Camb., M.R.C.P. Lond.
Physician to King Edward VII Hospital Windsor.

THE association of hæmoglobinuria with exertion is well recognised. In Germany it has been described under the name *Marschhæmoglobinurie* and in America very full notes of a case have been given by Watson and Fischer (1935). MacManus in this country in 1916 reported three cases in army recruits, and Wits in 1936 published notes of two cases. In all of them, with the possible exception of the army recruits of MacManus, the symptoms followed muscular exertion and had no relation to exposure to cold.

It has been noticed on several occasions that only certain kinds of muscular exertion will produce symptoms in some individuals. For example the patient described by Watson and Fischer was under observation for many weeks and hæmoglobinuria occurred only after walking. Meyer points out that other kinds of exercise such as cycling do not lead to hæmoglobinuria.

The following notes are of two cases of hæmoglobinuria in public school boys. Both were in the habit of playing strenuous school games and running long distances on grass, without symptoms, but attacks followed immediately after running on a hard road.

CASE 1—A schoolboy, aged 17½, complained on Feb. 16th, 1916, of passing blood in the urine after running in the final heat of a mile race on the road. He had noticed it on two previous occasions after running on the road. The race was at 12.30 P.M. and the urine passed at 2.30 was dark brownish red and gave a strong reaction with the guaiacum test for blood. It contained a great deal of albumin and many urate crystals, but no red blood corpuscles. At 6 P.M. it was slightly smoky and contained a quantity of albumin. At 10 P.M. it was clear and of normal appearance and free from albumin, and remained so. On March 1st after running in a half-mile race on grass the urine was normal and contained a faint trace of albumin only. Several tests were made later after exercise, but hæmoglobinuria was never found again.

This boy was in hard training for athletic sports and was in the habit of taking much exercise. Hæmoglobinuria was never noticed except on these occasions after running on the road. In December, 1936 (twenty years later), he reported that he was perfectly well and that the symptom had never recurred, though he had played football, cricket, and squash racquets in the interval.

CASE 2—A schoolboy, aged 17, after having played in several preliminary football ties ran about two miles on the road as part of his training for the final. Immediately afterwards he passed urine that was slightly turbid and almost black and gave a strong guaiacum reaction. After centrifuging, the supernatant fluid was dark brown, and the deposit consisted entirely of granular detritus. No red blood corpuscles were found and no pus or crystals. Two hours later the urine was sherry coloured, and contained a trace of albumin but no red corpuscles. After another two hours it was pale, perfectly clear, and apparently normal.

This patient too was in hard physical condition and had been playing strenuous football for many weeks and running long distances without symptoms. The only occasion on which hæmoglobinuria was noticed was after this run on the road. The blood Wassermann reaction was negative.

It seems unlikely that this sequence of events can be nothing more than a coincidence, but it is difficult to see the connexion. Lordosis has been suggested as the cause which precipitates an attack. Neither of these patients had marked lordosis, and there seems no reason to think that running on a road should induce a more lordotic posture than running on grass. No tests were carried out to prove whether the pigment was blood hæmoglobin or muscle hæmoglobin. Neither patient had any symptoms other than the hæmoglobinuria, and neither was anæmic nor jaundiced. The rareness of hæmoglobinuria is general and this association in particular seems perhaps to justify these notes.

I am indebted to Mr. Herbert Perkins, pathologist to the Paddington Green Children's Hospital, for his help in urine analyses.

RUBBER AND SPERM-SURVIVAL

By R. M. RANSON

(From the Sir William Dunn School of Pathology, Oxford)

IN the annotation on Dr. Huhner's work on sperm survival in *THE LANCET* of May 22nd it is stated that sperms may die from the action of some chemical used in the manufacture of rubber condoms. Dr. Huhner does not mention this in the paper referred to, but he states that the dusting powder used to ensure easy adjustment of the condom kills the sperms. These are subjects which have been studied for some time in the course of the general research on chemical contraception carried out under the direction of Mr. John R. Baker, D. Phil., in the Sir William Dunn School of Pathology.

It has been found that ordinary dusting powder (french chalk) is without effect on sperms, but certain sorts of rubber are spermicidal. There is a great difference in various sorts of rubber in this respect. The most spermicidal appears to be latex rubber, for example Durex, made by the London Rubber Co., and the test-ended sheaths for use in the tropics made by the Hygienic Stores Ltd. The least spermicidal are the grade A 1 and grade 2 test-ended

sheaths made of moulded rubber by the Hygienic Stores. The following are intermediate Lambutt No 7 made by Lambert's Ltd. and the following products of the Hygienic Stores. Luon X.L. Inflated Para rubber No 2 washable moulded rubber trans parent Ceylon rubber Paragon Paragon dyed red.

In my experiments sperms are caught in sheaths of the least spermicidal sort, transferred at once to glass tubes and brought to the laboratory. Here they are put into various sheaths in a damp chamber maintained at 37° C. For economy I put only 0.5 c.c. of semen in each sheath. In the highly spermicidal sheaths nearly all the sperms are dead in three-quarters of an hour and all life is extinct in one hour. In the scarcely spermicidal sheaths there is still full activity at 1½ hours and the sperms are not all dead until 5 hours. The control sperms in a glass tube at 37° C are still at full activity at 5 hours.

Research is in progress with a view to finding out whether the spermicidal powers of certain sorts of rubber can be utilised as a means of contraception.

When a physician wishes to examine a specimen of semen for motility he should get his patient to use a sheath of the least spermicidal sort and to transfer the sperms soon after coitus to a clean glass specimen tube provided with a ground glass stopper or waxed cork. This should be left at room temperature until examination which should be done after the sperms have been warmed up to 37° C for ten minutes. With this technique the sperms of some donors will still show full activity at 30 hours after ejaculation and a few will still be alive at 3½ days.

I wish to thank Mr. J. Tynen for much practical assistance and the Hygienic Stores Ltd. for providing material. The work was done under the auspices of the Birth Control Investigation Committee.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTIONS OF EPIDEMIOLOGY AND OF MEDICINE

At a combined meeting of these sections held on May 28th, with Surgeon Captain S. F. DUDLEY in the chair a discussion on

Air Conditioning

was opened by Mr. R. FREDERICK, an Admiralty research worker who dealt with the subject of ventilation. His experience he said had been gained with ships and naval establishments. In ships special attention had to be paid to ventilation because the living space was so limited. Samples of air were sent for examination to the Royal Naval Medical School, Greenwich, or when for any reason the conditions had to be examined in situ a transportable laboratory was used. This with its equipment he described and demonstrated. A reliable and quick means of determining respiratory impurity was, he said, by carbon dioxide determination. A proportion of 12 parts of carbon dioxide per 10,000 was quite harmless. If the respiratory CO_2 in that room were increased to 200 parts per 10,000 nobody would be aware of it. It might be noticeable at 250 parts, but it was only when CO_2 exceeded 300 parts per 10,000 that the effect became really appreciable. Anyone who had lived in an atmosphere where the respiratory impurity was 500 parts per 10,000 would probably remember it for the rest of his life. The apparatus used was devised by J. S. Haldane, the ordinary form of this apparatus read only to 100 parts which was ample for civil purposes, but a more refined apparatus was necessary for Service purposes. The amount of air which must be supplied to keep the CO_2 down to a proper level was from 2000 to 3000 cubic feet per man per hour. This however was more and more coming to be regarded as only one factor; no less important was the question of floor space.

For the maintenance of comfort and a feeling of well-being the first requisite was a moderate temperature with a moderate humidity. In temperate climates the dry bulb was of chief interest and in hot climates the wet bulb. It had been suggested that the ideal was a temperature of 60° F. and 50 per cent relative humidity, but most people would find that

too cold. The greatest measure of agreement would be thought, be accorded to the following

For hard work	60-62° F
For sedentary work	62-64° F
For leisure	64-66° F

with a relative humidity of 70 to 75 per cent. The wet-bulb figures given by Haldane had been widely accepted; they were

In still air	{ 88° F for sedentary work,
	{ 78° F for hard work,
In moving air	{ 93° F for sedentary work
	{ 85° F for hard work.

He thought these temperatures could be placed considerably higher.

Temperature and humidity afforded a certain amount of information whether conditions were such as to interfere with the loss of body heat, but there was another factor to be considered. The beneficial effect of air movement was due to its continual dispersal of the envelope of hot air between the clothes and the skin of the individual and to the increased effect of convection currents—in other words, the cooling power of the air had been increased. Apart from the relation of respiratory impurity ventilation could be assessed by the dry and the wet bulb temperatures, the relative humidity and the air movement. In America this combined effect had been termed the effective temperature and a comfort zone had been worked out which for various reasons was not applicable in this country.

Mr. C. W. PRIOR (Home Office) dealt with air conditioning in factories. The outstanding feature of the industrial field was of course the variety of conditions in various industries. One ship's cabin was much like another theatre compared with theatres and schools with schools, but factories could not be compared as the conditions under which they had to be run imposed upon them by the nature of the processes covered a wide range. In the term factory he included flour mill, cement works, dye works, gas works and electrical stations, and many diverse industries. A proportion of these could be air conditioned, but it was obvious that in any large number of factories or parts of factories air conditioning would not be adopted nor recognised as within the realm of practical politics. The problem in its physical aspects was difficult and the advent of the large single-story partitionless factory had not made it easier. On the other hand there was a large range of factory premises to which air

conditioning could be applied just as well as to non industrial premises, and many plants had been installed for partially conditioning the air supply, including plenum installations for supplying warm air in cold weather, particularly in industries in which light work was carried on. A number of plenum installations were also in use for supplying cool air to furnace workers. Air exhausting plants were used for extracting deleterious products from manufacturing processes, and might be responsible for the whole of the ventilation since the air extracted must be replaced. The regulation of humidity in this country had so far not been adopted in the ordinary factory. There was nothing comparable with the practice in the United States and Canada. If ordinary factories were adequately ventilated as the law required, the problem of humidity was (and would continue to be) regarded as of little significance. The new Factories Bill would assist in bringing about more efficient air conditioning in many workrooms. Dust of any kind must now be extracted where practicable if produced in quantity—the provisions in force were limited to harmful dust. In not a few factories advance had already been far reaching. Even in workrooms where peculiar difficulties had to be overcome, and dangerous processes were carried on, good conditioning might be found. Thus had come about because employers had agreed to the provision for higher standards of ventilation while not neglecting temperature requirements. Radiation was not an air conditioning factor, but one to be taken into account in any relative temperature evaluations. He concluded by asking to what extent in factories complete air conditioning should be adopted or recommended, even where it might be adopted with advantage, he was doubtful if the regulation of humidity was in general necessary.

Prof E. M. FRAENKEL discussed allergic conditions and air purification. Pollution of the air was of importance in different types of allergic complaints such as hay fever, asthma, and some cases of urticaria and eczema. The types of allergens which were effective were either outdoor or indoor impurities. The latter might be brought in by air or clothing or might consist of allergen forming material already present (horsehair, feathers, woollen carpets, moulds, rugs, and the like) or of breakdown products formed from innocuous indoor material by the action of moulds. Air purification in the case of allergic patients was not identical with air conditioning. The walls and the contents of the rooms must be constructed of suitable material, as indoor allergens were a frequent source of trouble. Impurities from outside might be solid particles, fine droplets of moisture, or even gases and vapours—mostly a combination of two or more of these. Various methods such as filtration, freezing, washing, or the influence of an electrostatic field had been devised for air purification. He had himself worked out a special method of chemical and physical filtration for use in connexion with masks, sleeping bags, and cubicles for the diagnosis, prophylaxis, and treatment of allergic cases. This method was demonstrated by a film of an asthma subject sensitive to dog hairs.

Sir WELDON DALRYMPLE CHAMPEYS called attention to the psychological factor in ventilation. In the tropics he had found that white people stood up to moist heat badly, not only because they did not sweat satisfactorily, but because they were depressed by the idea that the atmosphere they were living in was too hot and too moist. He had been struck by the reactions of his companions to increasing heat and humidity, not to be accounted for on a purely

physical basis. People of phlegmatic temperament stood up better to increasing heat. The same sort of thing was found in dug outs in the war. Some men could not stand them, not on account of claustrophobia, but because they thought the place was getting unhealthy. He had also noticed in cabins in ships in hot weather when the portholes had to be kept closed how people felt as if they were being suffocated. The importance of odours in the air could not be disregarded. Odours gave some people the impression that they were being suffocated and made them very uncomfortable, although the actual physical conditions were not unsatisfactory.

GERMAN HÆMATOLOGICAL SOCIETY

INTERNATIONAL CONGRESS AT MÜNSTER

THE first meeting of the newly formed German Hæmatological Society took the form of an international congress held at Münster, Westphalia, from May 10th–13th.

Prof VICTOR SCHILLING (Münster), who presided, gave an introductory address on the historical development and modern applications of scientific hæmatology. Outlining the gradual advance of hæmatological knowledge until the end of the nineteenth century, he dealt in detail with the work of the great hæmatologists of the early twentieth century and the foundation of the old German hæmatological society in 1908. He then reviewed the advances made in the last thirty years which would provide the themes for discussion at the congress.

The scientific communications were opened by a paper by Prof LUDWIG ASCHOFF (Freiburg), who discussed the

Monocyte Question

from the anatomical and histopathological standpoint. Reviewing his own work and that of others he came to the conclusion that his original view that monocytes were derived from tissue histiocytes or sinus lining cells could not be maintained and that it was most probable that they arose from undifferentiated mesenchymal elements in lymphoid tissue and were directly transferred to the blood stream as monocytes were never found in the lymph. He emphasised the distinction between monocytes and lymphocytes and went on to discuss the relationship of the plasma cell with the lymphocyte, questioning whether the marrow plasma cell was identical with that of the connective tissue, and suggested that there was still much work to be done both from the histological and cytological aspects in glandular fever and experimental *B. monocytogenes* infections.

THE PRESIDENT surveyed the clinical aspects of the subject and held that few cases of true monocytic leukaemia had been described, his criteria being in addition to the blood picture, a leukæmic infiltration of the organs. Rather surprisingly he maintained that the bone marrow should show no alteration. Dealing with other forms of monocytosis he mentioned the false monocytosis sometimes found when the specimen of blood has been collected from the ear, it only occurs if the first drop of blood is used for examination and is most common in cyanotic patients. He suggested that this was a static phenomenon and produced convincing evidence that the cells were not shed vascular endothelium as has been suggested.

Dr E LAUDA (Vienna) reviewed the relation of the spleen to blood disorders laying especial stress on the evidence for an endocrine function which controlled bone marrow activity and the part played by the spleen in iron metabolism. He believes that aplenic siderosis is indicative of cellular dysfunction rather than increased activity and that there may be both active and passive hemolysis in the spleen, of which the latter is the more common.

The afternoon was occupied by a series of admirable papers on the

Pathology of the Bone marrow

Prof. H SCHULTEN (Hamburg) described the normal cytology and technique of sternal puncture. He upheld the triaxial view of hemopoiesis but questioned the existence of the haemocytoblast. He was in doubt as to the difference between a pro-erythroblast and pro-megaloblast although emphasising that the megaloblastic family of erythrocytes must be clearly distinguished from the normal erythroblastic series. He suggested that mature cells did not remain long in the marrow.

This communication was followed by an account of the pathology of the bone marrow by Prof HENNING (Fürth) which was one of the best contributions to the congress. He described the changes in sternal puncture preparations found in many blood diseases. In pernicious anemia, for example in addition to the megaloblastic proliferation, there are abnormalities in the granulocytes and megakaryocytes in both of which hypersegmented giant forms are seen these revert to normal after liver therapy. This change together with an enormous erythroblastic activity can be seen twenty four hours after the first injection of liver. Prof Henning doubts whether one should accept the idea of two distinct erythrocytic series—the megaloblastic and erythroblastic. He said he had observed a reduction of megaloocytes in the circulating blood before the increase of the reticulocytes and although there were equally striking alterations in the granulocytes after liver therapy yet it had never been suggested that there were two families of these cells.

Arsenic was found to produce an increase in ripening of the megaloblasts in pernicious anemia but only of pathological ripening with the result that there was a considerable increase of megaloocytes. Marrow puncture in the leukemias was of little value except in the aleukemic cases when it was of great diagnostic help. In agranulocytosis the cytology varied in some cases there was an absence of free elements with a proliferation of reticulum cells—this was the so-called empty marrow. In other cases there was an apparently normal marrow but the most mature cells were lacking; and in the third type there was a great increase in myeloblasts or pro myelocytes. In every case the cells were abnormal showing vacuolation and nuclear changes. In glandular fever there was no cellular proliferation in the marrow and the abnormal cells found there were derived from the circulating blood. Prof Henning described the various changes found in infectious diseases and the value of sternal puncture in the diagnosis of parasitic diseases—malaria kala azar &c. Finally he discussed the value of bacteriological culture of bone marrow. In a series of 350 cases of typhoid fever a positive culture was obtained from the sternal puncture material before a growth could be obtained from the circulating blood.

Prof ROTH (Zurich) discussed the mechanism controlling the entry of cells into the circulation and suggested that the bone marrow could be regarded as a closed or controllable system whereas the spleen

was an open system in conditions such as the leukoses in which there was myeloid proliferation in the spleen and liver the abnormal cells in the circulating blood were derived from these organs rather than from the bone marrow.

Dr R KLIMA (Vienna) described the changes in the bone marrow in multiple myelomatosis and Hodgkin's disease. In cases in which there was clinically a localised myeloma in one of the long bones he had invariably found myeloma cells in the sternal puncture. He regarded myelomatosis as a systematised proliferation analogous to the leukoses and suggested that the myeloma cell was closely related to the marrow plasma cell which he derived from the myeloblast but distinguished from the plasma cell found in the connective tissue in chronic inflammatory conditions. In Hodgkin's disease although at autopsy the bone marrow was involved in 70 per cent. of cases no characteristic changes could be found by means of sternal puncture during life. Dr Klima believed however that diagnosis could be made by means of lymph node puncture; but neither his criteria nor his conception of the typical cytology appear to correspond with the present pathological views.

The second day opened with an account of

Blood platelets

by Prof HITTMANN (Wels Austria). He discussed difficulties of enumeration and suggested that for ordinary purposes a visual estimation of their numbers in a supravitral preparation was sufficient. When a numerical count was made the method must be stated owing to the enormous variation in normals with the different techniques (250 000 Ponio might read 900 000 Hoffmann). Prof Hittmann upheld Wright's theory of a megakaryocytic origin for blood platelets although as he admitted he was putting his head into the lion's mouth by doing so at Münster (Prof Schilling maintains that the platelets represent the shed nuclei of the erythrocytes and that megakaryocytes are merely histiocytes in nature).

In bone marrow studies, however the number of platelets was the same as that of the circulating blood and the formation of platelets from megakaryocytes could only be observed under abnormal conditions. Prof Hittmann upheld Rohrer's view of explosive rupture of the megakaryocyte at the time of formation. He discussed the changes in platelets in various diseases and their relation to blood coagulation which he felt was not understood. An animated discussion followed the question of the President put forward his views on the method of rapid fixation of the platelets which he believed he could substantiate by experiment. Prof VORR (Solingen) showed that platelets contained no thymonucleic acid although in the same medium those of isolated erythrocytes were found in large quantities of it.

Prof WERNER SCHULTEN (Hamburg) discussed
The spleen

with special reference to the changes in the spleen in agranulocytosis. He described the changes in the spleen in agranulocytosis and suggested that the platelets might be derived from the spleen. He discussed the changes in the spleen in various diseases and their relation to blood coagulation which he felt was not understood. An animated discussion followed the question of the President put forward his views on the method of rapid fixation of the platelets which he believed he could substantiate by experiment. Prof VORR (Solingen) showed that platelets contained no thymonucleic acid although in the same medium those of isolated erythrocytes were found in large quantities of it.

water, or even under heparin, however, hirudin which acted on the capillaries as well as on the coagulation mechanism prolonged the bleeding time, further, the bleeding time is not markedly prolonged at 0° C although blood does not coagulate at that temperature

Leucocytes —Parasitology

In the afternoon Prof HOFF (Würzburg) discussed the dynamics of leucocyte regulation and Dr THADDEA (Berlin) described changes in the leucocyte adrenaline response in disorders of the suprarenals. In Addison's disease the normal leucocytosis obtained after the subcutaneous injection of 1 mg of adrenaline is absent but treated cases give a normal reaction, on the other hand in cases of cortical adrenal tumour the leucocyte adrenaline reaction is exaggerated.—Dr UNDRITZ (Orselina Locarno) described a series of cases showing the inherited Pelger Huët anomaly of the granulocytes and Prof ADLER (Switzerland) described a new form of inherited granulocytic abnormality in which the nuclei were normal but the cells showed large darkly staining granules.

Prof KIKUTH (Elberfeld) showed that in malarial treatment no drug has been found which attacked the free merozoites. Plasmoquine destroyed the sexual forms, and Atebrin and quinine the asexual forms.—Following this Prof. P. MUEHLENS, director of the tropical institute at Hamburg, demonstrated some excellent cinematographs of the life cycles of malaria, leishmaniasis, and various types of spirochetes and filariae.

The last day was devoted to

Anæmia

The PRESIDENT read a paper on the structure of the erythrocytes. He dealt particularly with the relation of reticulation to polychromasia and described the peculiar inclusions found in methemoglobinæmia and the significance of bartonella like bodies found in the erythrocytes in anæmia.

Prof E. MEULENGRACHT (Copenhagen) dealt with pernicious anæmia. Recapitulating his experimental work on the pig stomach (see *Lancet*, 1935, 1, 493) in which he showed that intrinsic factor was only to be found in the pylorus, duodenum, and cardiac region and was absent from the fundus, he went on to describe his observations in a number of stomachs obtained post mortem from pernicious anæmia cases. These showed a severe atrophy of the fundic region with intestinal heterotopia but practically no change in the pylorus or duodenum—a finding completely the reverse of that which he had anticipated from his animal observations. However, it had been shown that the proportionate amount of intrinsic factor per c cm was unchanged in pernicious anæmia but the total quantity of gastric juice was reduced and he was at present investigating the amount of pyloric and Brunnerian glandular substance in the pernicious anæmia stomach. He believed that regular oral administration was preferable to occasional injections both from the point of view of cost and in minimizing the possibility of nervous changes. He found that a subtherapeutic dose of stomach powder (5 g daily) when taken with liver residues (after extraction of the active factor) which were inactive alone produced a therapeutic result far greater than could be explained by a mere additive effect.

In the discussion which followed it was agreed that oral administration was mostly preferable to parenteral but it was imperative that the anti-anæmic substance should be taken in the form of

medicine and not as a foodstuff which might be shared with the rest of the family, and in many cases it was only by means of parenteral administration that one could be sure that the patient was receiving adequate and regular treatment.

Dr H. J. WOLF (Göttingen) read a preliminary communication on the experimental anæmia produced in rabbits by means of typhoid toxin, which was only controllable by the administration of active liver material and might be made to serve as a biological method of assay. However, there were considerable difficulties, the chief being the severe illness produced in the animals which often resulted in a fatal outcome before the effect of the anti-anæmic substance could be judged.

Dr KLIMA discussed the classification of the anæmias and suggested that it was impossible to group them solely according to cytological, etiological, or therapeutic criteria and that it was more valuable to consider them from the point of constitutional and familial aspects.

The concluding communication was by Dr L. HEILMEYER (Jena) on the iron deficiency anæmias. He dealt in particular with the iron content of the serum in various conditions, this was estimated photometrically and in males found to be 100–150 γ per cent and in females 50–100 γ per cent, but this difference between the sexes disappeared after the menopause. In a normal person, said Dr Heilmeyer, the serum iron is fairly constant in value, the iron depôts being full and any excess iron being excreted by the gut and skin, never by the urine. However, in iron deficiency anæmia the serum iron is low and the deficiency of storage may be demonstrated by the intravenous administration of 10 mg of iron and repeated estimations of the serum iron. In a normal person the serum content rises to 400 γ and then falls very slowly, in deficient iron storage it rises to 180 γ and then quickly falls. In acute infections the serum iron drops to a very low figure even when no anæmia is present and large quantities of iron must be given to maintain it at a normal figure during the infection. The explanation of this is obscure but may be related to the increased activity of the reticulo-endothelial system and it is known that a siderosis of the spleen is not uncommon in infections. In untreated pernicious anæmia, the serum iron is almost invariably high and this drops to a normal figure after treatment but in those cases in which there is deficient iron storage it will drop below normality and it is these cases whose recovery is delayed until iron is given in addition to anti-anæmic principle. Dr Heilmeyer pointed out that the hæmatological criteria for iron deficiency were hypochromia and plancytosis. Microcytosis was not invariably associated with iron deficiency. As to the form of iron therapy, in most cases it made little difference provided it was given in sufficient amounts and although the ferrous salt was biologically active, ferric salts were readily reduced, probably with the aid of vitamin C. In some cases it was expedient to give a ferrous salt and in severe dyspepsia intravenous iron was to be recommended.

At the conclusion of the meeting Prof MEULENGRACHT expressed the appreciation of the foreign delegates from the fifteen countries represented at the conference of the arrangements made.

Dr STORTI (Rome) announced that the Italian Hæmatological Society, of whom he was the representative, would hold an International Congress in Rome in 1941 and invited the delegates present to attend it.

GENERAL MEDICAL COUNCIL

SUMMER SESSION, MAY 26TH-29TH 1937

New Penal Cases

(Concluded from p. 1349)

MEASURE FOR CANVASSING

The Case of *Bakhtawar Singh Jain* registered as of Hindustan House, Weoley Castle-road, Selly Oak, Birmingham L.R.C.P. Edin 1921 L.R.C.S. Edin. 1921 L.R.F.P.S. Glasg 1921 who had been summoned to appear before the Council on the following charge—

That being a registered medical practitioner you have canvassed the patients of other registered medical practitioners for the purpose of inducing them to become patients of yours and in particular (1) on Oct. 31st 1936 canvassed Albert Bird obtained from him the medical card issued to him as a person insured under the National Health Insurance Acts and procured his transfer to you as an insurance practitioner (2) in or about October 1936 canvassed Arthur Eccleston and his wife Doris Eileen Eccleston, and endeavoured to obtain them and their child as patients (3) in or about September 1936 on two occasions canvassed Winston Haig Evans with a view to inducing him to transfer to you as an insurance practitioner (4) in or about October 1936 on two occasions canvassed Mrs. Florence Jones with a view to inducing her and her husband and three children to become patients of yours. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

Dr. Jain appeared accompanied by Mr. Arthian Davies counsel instructed by Messrs. Cole and Matthews agents for Mr. Frank Rowland solicitor Birmingham. The complainant, Dr. Francis Ronald Gedye, a local practitioner was represented by Mr. W. A. Macfarlane counsel instructed by Messrs. Le Brasseur and Oakley solicitors.

Mr. Macfarlane did not call evidence to support the charge of canvassing Albert Bird. He called Mrs. D. E. Eccleston who said that in October 1936 her doctor and her husband had been Dr. Gedye. She had just returned from hospital and one afternoon Dr. Jain had knocked on the door and she had opened it and spoken to him on the door step. He had asked her whether she had a doctor. She had replied Yes. He had then asked her whether her husband had a doctor and she had again answered Yes and that they were attended by Dr. Gedye. Dr. Jain had asked if she would like her daughter to go on his panel and had given her a professional visiting card. This she had later burnt. Her husband, who had been sitting in the front room asked who was there and when she had told him that it was Dr. Jain he had shouted Tell him to clear off.

Cross-examined by Mr. Davies she said that respondent had never attended her daughter nor had she ever taken the child to his surgery. He had told her that he had been attending her next door neighbour a Mrs. Kesterton who had told him that Mrs. Eccleston was ill and asked him to call on her. Mrs. Kesterton had never said anything to her about asking Dr. Jain to call.

Arthur Eccleston her husband said in evidence that he had known the doctor by sight. In this conversation all of which he had overheard the doctor had asked her if she and her husband would go on his panel and whether they would like the child to go on it as well. As Dr. Jain was leaving he had said I shall have to call round again. Witness had replied You'd better not or you'll get into

serious trouble. On cross-examination he said that he had made a statutory declaration at the request of a gentleman from London. Mr. Davies put to him a document which he admitted writing and signing on a later date. It said that his wife told him that the doctor had been sent by Mrs. Kesterton that he had not warned the doctor he would get into trouble; that the doctor had not asked him and his wife to come on his panel and that the allegations of canvassing had been put into his mouth by a solicitor's clerk. Asked the circumstances in which he had written and signed this document, he said that some weeks ago a woman who kept a small draper's shop some distance away had unexpectedly sent for his wife and offered her work on two mornings a week. Three days before the hearing she had asked him and his wife to supper they had gone there, and afterwards Dr. Jain had walked in and talked about the case showing them some papers and saying that he was a good doctor and there was no reason why witnesses should go to London to give evidence against him. He had also said that he was taking proceedings for slander against another doctor and that if he did not win his case before the G.M.C. the witness would be brought into the slander case and get into serious trouble. Witness had therefore considered that the best thing to do was to wash his hands of the G.M.C. case. He had written the contradictory statement at the respondent's dictation.

Mr. W. H. Evans said that from June 1930 onwards he was on the panel of a Dr. Thomas. He had first met Dr. Jain in July in his lodgings but had not spoken to him. They had conversed in September at the same place. Dr. Jain had asked him on whose panel he was and then whether he would like to change over to his panel. Witness had refused but several times after that his landlady had tried to persuade him to change. On the first occasion Dr. Jain had asked the witness for his medical card. In cross-examination he said he had a brother called David but that the respondent was not asking him about David's card. After he had made a statutory declaration a gentleman whom he did not know had induced him to sign a contradictory statement of which part was true and part was not as he had got timid. This gentleman had told him that he would be the only one going to London. Respondent had not said he had been asked to return witness's medical card.

Mrs. Florence Jones said that in the latter half of 1936 she had had no doctor but her husband had a panel doctor. They had recently moved to their present house. A fortnight after they had moved in Dr. Jain had spoken to her on the doorstep and asked her if she would like to sign on with him. She had said No she would sign on with another doctor before she would sign on with him. He had given her a card which she had burnt. A week later Dr. Jain had again asked her to come on his panel but her husband had said that they had already signed on with another doctor. In cross-examination she said she did not know whether respondent was attending her next door neighbour or another neighbour Mrs. Tacey.

Mrs. Ellen Atterbury said she had known Dr. Jain by sight and had moved to her present address at the end of August 1936. She and her husband then already had panel doctors. Dr. Jain had called at her house some time in October and her small daughter had admitted him. Witness had told him that her husband was in town on business. He had remarked how nice the front lawn was looking. He had gone on to say that he was attending a child

in another street, but that her child looked healthy enough. He had left his card for her husband and had called back again the same evening. In cross-examination, she said that Dr Jain had not called for the purpose of seeing her husband about his garden.

Dr Jain, giving evidence in his own defence said that he had first seen Mrs Eccleston when he was attending Mrs Kesterton's child. Mrs Kesterton had told him that Mrs Eccleston wanted a doctor. He had seen Mrs Eccleston standing at her door, she had greeted him, and he had entered into conversation with her. He had once treated her child in his surgery, on June 27th, 1936, and the visit had been entered in his day book, which he produced. He had asked Mrs Eccleston how she was and she had replied, and said she had a doctor of her own. He had asked after the child, and she had recalled to him the day she had brought the child to the surgery, she had said that she hoped, if it got ill again, he would not mind her bringing it back. He had not seen her husband nor given her a card, nor indicated that he wanted to attend on her child. The lady who kept the drapery shop had been one of his patients and had planned the meeting of her own accord. Mr Eccleston had told him that he had been pestered for the last few weeks by solicitors and their clerks to go to London and wanted to wash his hands of the whole affair, because he had made a statement which was not correct but had simply been put into his mouth. Dr Jain replied that if he signed statements at all he had better write the truth then and there. He had written it in his own words and handwriting, and no part of it had been dictated to him.

Dr Jain said he had spoken to Mr Evans thinking that he was David Evans, a brother who had been his patient since August. The Birmingham Insurance Committee had twice written to him asking him to return David Evans's medical record card, and he had therefore said to Mr W. H. Evans that he had been asked to return his medical card. He put in evidence the letters from the committee. Mr Evans had replied that he must have mistaken him for David. He had not asked Evans to become his patient. Dealing with Mrs Jones's evidence, he said that one day on his way to his surgery he had been asked by Mr Jones, whom he had not then known, whether he was treating Mrs Facey's child, and he had replied that he was. Mr Jones had then said that Facey had spoken to him about the respondent and that one of these days Jones would come to see the respondent, for he had just moved away from his present doctor and would like to sign on with respondent Mrs Jones, who was standing by, had then said she had a nasty cold and would come to see respondent. He had not asked her to sign on. He had not seen either of the Jones's after that. The Atterburys lived next door to the Faceys, whose child he was attending. Mr Atterbury had on one occasion been working in his front garden and had greeted respondent, who had complimented him on the look of the garden. Desiring to put the garden of his surgery in order he had called a few days later to see if Atterbury would work on it. He had found Mrs Atterbury in and had left his card, and in the evening he had called again and spoken to Mr Atterbury about the garden. He had never invited any of the witnesses to come on to his panel.

Cross examined, he said that he had been surprised to find the Ecclestons at the house of his patient, though he had known they were to be witnesses before the G.M.C. Mr Eccleston had said that he

wanted to hear the true story from respondent, as he had been pestered by solicitors. Respondent had shown him some documents to prove the allegations were untrue. The brother of one of his patients, a Mr Waterfield, had brought him Evans's statement. This patient had asked Evans about his evidence and Evans had replied that his statutory declaration had been made under influence and that he was prepared to give the true facts. The patient had then put down his statements and handed them to respondent.

His day book showed receipts of money on each day. These were entered at the time of receipt therefore they were presumably in chronological order.

The Legal Assessor pointed out two dates in 1936 and asked him whether the 6 had not been altered from a 7. Mr H. L. Eason put to him that the last entry on one of the left-hand pages was the name of Joyce Eccleston, the next entry at the top of the right hand page bore a date which had been altered from a 7 to a 6, and lower down another entry had been similarly altered. Lower still there were two more entries, corresponding in sequence of date but purporting to be 1937 and not 1936. On the next page two other dates had apparently been altered. All these entries were subsequent to the entry of Joyce Eccleston, which would then correspond to the date on which respondent had said he had seen her. In reply, respondent said he must have copied this material from another book which he had not with him.

The Legal Assessor: "Why then did you get the entries out of order?"—"It must have been through a slip of the pen."

"They are all slips of the pen, are they? Is that your explanation?"—"Yes."

Re-examined by Mr Davies, he said he kept two books for income tax purposes. He had not altered this book to show that he had attended Joyce Eccleston in June, 1936. The entry had been made on June 27th, 1936.

After deliberation in camera the President announced that the second, third, and fourth charges had been proved to the satisfaction of the Council and the Registrar had been ordered to erase the name of Bakhtawar Singh Jain from the Register.

CHARGES OF CANVASSING DISMISSED

The Council dismissed the charges brought against Hugh McNicholl, registered as of c/o 105, London road, King's Lynn, Norfolk, M.B., B.Ch. 1933, N.U. Irel, who had been summoned to appear before the Council on the following charge—

That being a registered practitioner you have systematically canvassed personally and/or by means of an agent or agents for the purpose of obtaining patients, and in particular (1) in 1936 or 1937 or in both of those years, canvassed patients of Guy Kinner a registered medical practitioner, by furnishing or causing to be furnished to them professional cards on which your name, qualifications, address and telephone number were printed, (2) in 1936 or 1937 canvassed Mrs Stacey by causing one of the professional cards to be furnished to her, and by endeavouring yourself to obtain from her the medical card issued to her husband as a person insured under the National Health Insurance Acts (3) in or about March 1936 canvassed by means of an agent Mrs Bertha Florrie Gardiner and thereby obtained a child of hers as a patient, (4) in or about March 1936 canvassed the said Mrs Bertha Florrie Gardiner and thereby obtained the transfer to yourself as an insurance practitioner of her husband Thomas Reece Gardiner, a person insured under the National Health Insurance Acts (5) in or about March 1936 employed the said Mrs Bertha Florrie Gardiner as an agent for the purpose of obtaining patients by means of the

distribution of professional cards which you handed to her and on which your name, qualifications, address, and telephone number were printed. (6) In or about May 1936 attempted to employ the said Mrs. Bertha Florrie Gardiner further as an agent for the purpose of obtaining patients. (7) In the summer of 1936 employed Mrs. Collins as an agent for the purpose of obtaining patients by means of the distribution of professional cards which you handed to her and on which your name, qualifications, address, and telephone number were printed. (8) In or about February 1937 canvassed Mrs. Kimber by means of an agent by whom a professional card on which your name, qualifications, address, and telephone number were printed was furnished to her. (9) In or about December 1936 on two occasions canvassed Charles Hartridge by means of an agent by whom a professional card on which your name, qualifications, address, and telephone number were printed and furnished by him. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

The complainants were the London and Counties Medical Protection Society and members of the Council who were also members of that society withdrew. The complainants were represented by Mr. Macfarlane, instructed by Messrs. Le Brasseur and Oakley, and Dr. McNicholl appeared, accompanied by Mr. Charles Davis, solicitor of Messrs. Bulmerig and Davis.

The first witness called in support of the charges was Dr. Guy Kinnear, a practitioner of Nottingham, London, S.E., who said that he had started practice in that neighbourhood in 1935. The respondent had come afterwards and lived about a mile away. The patients who would give evidence lived on a housing estate nearby. One other doctor lived in the estate, but neither witness nor respondent lived there. About a year ago a Mr. Bailey who with his wife and daughter had been witness a patient for some time but was now dead, had brought witness a professional card of the respondent (put in evidence). A Mr. Kimber who would give evidence was also a patient of the witness.

Mrs. Gardiner said she had moved to her present address in March, 1936. A few days afterwards her little girl had had an accident in the street and her face had been cut. A woman had suggested that witness should take her to the shilling doctor and had shown her a house where respondent was visiting at the time. The respondent had put a stitch in the child's face and witness had taken the child to his surgery to see him several times afterwards. On one of these occasions he had asked witness if she had a panel doctor. She had replied that her husband was on the panel of a Dr. Power but that his medical card had not come through. Respondent had asked the witness if her husband would go on to his panel and if so whether she would bring respondent the card. She had taken it to the respondent and he had kept it. Her husband had not transferred to respondent's panel until April 1936. Respondent had told her that he had come from Greenwich where he had been assistant to a doctor at £8 a week and was trying to work up a practice. He was earning only £4 a week, so he was anxious to get patients. He had given her about twelve small cards with his name, address, and telephone number. She had been in the habit of going to help women who were being confined and she had two of respondent's cards bearing the addresses of maternity patients whom she had been going to attend for him. Respondent had asked her to get patients for him. She had left two cards next door at the house of a couple called Bargarves, who had both become his patients; and at the houses of certain other persons who as far as she knew

were all on respondent's panel. They had been strangers to the district. She had given three of the respondent's cards to a solicitor's clerk. These were in evidence.

On a day in May 1936 respondent had visited her in her house and asked if she had any more patients for him. Her husband had said that this was not right and that doctors should not canvass. Respondent had answered that he must get patients as there was so much competition about, and her husband had said he would not permit her to canvass. She had got no more patients for respondent. She had seen one of the cards in the possession of Mrs. Collins, and had also seen Mrs. Collins visiting from house to house and leaving the cards. Mrs. Kimber was a friend of the witness and she had seen a similar card in her house.

In cross-examination Mrs. Gardiner said that at the time of her first visit with her daughter to the respondent she had told him about her affairs and her husband's complaints. Her husband was a shell-shock patient who suffered from neurasthenia. Respondent had not at the time asked her to bring her husband's card to the surgery. He had done this at about the third interview. She had told him that she understood the work of a handy woman and would like some work. Asked if she and the doctor had not fallen out, she replied that if this was the respondent's version of the facts it must stand as far as she was concerned, it was a secret. She agreed that she had fallen out with him but denied that she disliked him a good deal. She had walked with Mrs. Collins part of the way round the streets when Mrs. Collins was leaving cards at every house. Mrs. Collins had asked the inhabitants whether they had a panel doctor and had told them that the card was that of a thoroughly good doctor whom she could recommend. Witness admitted that she had been very concerned about finding the respondent's card with Mrs. Kimber, there were four doctors in the neighbourhood all of whom had to make a living; we make it our concern. She had kept the cards because there had been rumours going round that she did not know her work and was responsible for Mrs. Collins's illness after her confinement, also that she was going to be persecuted in one way and another and that respondent was going to bring an action against her for slander.

Respondent's solicitor admitted that two other patients had received cards from Mrs. Collins but denied that she was respondent's agent.

Dr. Charles Wortham Brook, another practitioner of Nottingham said that after receiving certain information from a patient he had written a letter to respondent saying that a woman had been trying to persuade the wife of one of his patients to go on respondent's panel and a king for respondent's explanation. He had had no reply until respondent had telephoned to him eleven days afterwards saying that he had sent a reply. He had since received respondent's cards from several of his patients. Respondent had over the telephone, suggested a meeting but after careful consideration witness had decided that he ought not to meet him alone. He had got into touch with other practitioners who had advised against the meeting. He had sent the papers to the Medical Defence Union but this body had taken no action as respondent was also a member. He was not co-operating with other practitioners to get respondent out although respondent was putting them in a difficult position.

Dr. McNicholl examined on his own behalf said that he had never authorised anybody to canvass.

or give his cards away. He had had a number of cards printed so that he might give them to patients to remind them of his consulting hours and address. He had not given them to anyone other than his patients. The first he had heard of the allegations had been in a telephone conversation with the secretary of the Medical Defence Union, whom he had afterwards visited. The secretary had told him that Dr Brook had complained that one of his patients had received a card, and advised him to find out the person responsible. The description of the woman who had given the card corresponded with that of Mrs Collins, his housekeeper. On returning home he had asked Mrs Collins if she had distributed cards, and she had denied it, but eventually she confessed that she had taken some of his cards out of his surgery to give to her friends. Mrs Collins had been a patient of his early in 1936 and he had attended her in her confinement. Mrs Gardiner had been looking after the house. He had had high words with Mrs Gardiner, after which she had never done any more work with him. He would not employ her any more, because she interfered with him. Mrs Collins had afterwards asked him for work and he had employed her, first as his charwoman in his surgery and afterwards, when he bought the house, as his housekeeper.

On the occasion when he had first treated Mrs Gardiner's child, she had asked him if he took panel patients, and said she would like to get her husband on to his panel, because he always had fits whenever he saw his present doctor. Later she had brought the panel card to him for signature. The only cards he had ever given Mrs Gardiner had borne the addresses of maternity patients to whom he was introducing her as a handy woman. He denied ever asking her if she had got him any more patients or telling her anything about what he was earning. In addition to a part-time assistantship he had two appointments, he was never short of money and in fact had soon been able to buy his house. Mrs Stacey had consulted him for a skin rash and he had prescribed injections. At one interview her husband had asked him if he was on the gas company's panel, and on hearing that he was had offered himself as a patient, and respondent had signed his card then and there. He had never at any time canvassed for patients. He had been warned against Mrs Gardiner by another doctor and would never have asked her to do anything for him. He had never employed Mrs Collins as his agent, and when he had found out that she had canvassed he had told her to go. He was retaining her for the time because she had no other means of livelihood.

Cross examined, he said that he had not received Dr Brook's letter until six days after its date. He had sent a reply saying that he knew nothing about the canvassing and could only suppose that it had been done maliciously, a copy of the letter was in evidence. Mrs Collins said in evidence that she had consulted respondent in March, 1936, and he had attended her in her confinement in September. Mrs Gardiner had been recommended to her by respondent, but Mrs Gardiner and respondent had quarrelled. Respondent had given her work and had lent her money. He had never given her any cards to distribute, but in her gratitude to him she had taken some cards without his knowledge and distributed them. He had discovered this and said he could not understand how people were getting his visiting cards. She had not at the time enlightened him, because she did not want to lose her sole means of support. He had, however, challenged her on a

later occasion and she had confessed. He had wanted to put her out of the house there and then, but she had persuaded him to keep her on, which he had done out of compassion.

Mrs Ivy Doyle said that she had called every day to set the respondent a house in order. Respondent had asked Mrs Collins in her presence if she had taken any cards out of the surgery, and Mrs Collins had denied it. Witness had afterwards asked her the same question and Mrs Collins had again denied it, but afterwards admitted it to the respondent. She had asked the witness to beg her off from dismisal.

Mrs Elizabeth Perrott testified that respondent had been attending her at her house when Mrs Gardiner had come and asked him to see her child. Mrs Gardiner had been very talkative and had given respondent her whole life history. Respondent had told her to bring the child to his surgery, she had not been able to understand the address, so witness had given her one of respondent's cards which she had by her. Mrs Gardiner had asked respondent if he would take her husband on to his panel.

A Mrs South also said in evidence that Mrs Gardiner had requested respondent to take her husband on to his panel.

Mr T C Smith, formerly the owner of respondent's house, said that he had given one of the respondent's cards to Mrs Kimber without respondent's knowledge, as Mrs Kimber had asked him for the address of a doctor to treat a sty in her eye. Mr Stacey said in evidence that he had gone on to respondent's panel of his own accord. He had previously had a card left at his house, but did not know by whom. Respondent had been attending his wife when he had transferred to respondent's panel.

After deliberation in camera, the President announced that the charges had not been found proved to the Council's satisfaction.

The Case of Albert Rudolf Rellum, registered as of 39, Dockhead, Bermondsey, London, S E 1, L R C P Edin, 1921, L R C S Ldn, 1921, L R F P S Glasg, 1921, who had been summoned to appear before the Council on the following charge—

That being a registered medical practitioner, you have canvassed the patients of Joseph Frelich, a registered medical practitioner with a view to inducing such patients to become patients of yours, and in particular (1) in or about the month of November 1936, you canvassed William Selley, a patient of the said Joseph Frelich, (2) in or about the month of November, 1936, you canvassed Elizabeth Selley, the wife of the said William Selley, a patient of the said Joseph Frelich, (3) in or about the month of November, 1936 you canvassed George Fred Selley, a son of the said William Selley and Elizabeth Selley, and induced him to become a patient of yours (4) in or about the month of November, 1936, you canvassed William John Selley, a son of the said William Selley and Elizabeth Selley, a patient of the said Joseph Frelich. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

Dr Joseph Frelich, a practitioner in Bermondsey, presented his own complaint, and Dr Rellum was accompanied by Mr John Ritchie, counsel instructed by Messrs Simon, Haynes, Barlas and Ireland.

Dr Frelich said that Dr Rellum had been his assistant but he had dismissed him early in March of the present year. Mrs Selley had called at his surgery and told him that the respondent had been canvassing members of her family, patients of Dr Frelich to become respondent's patients.

Mr and Mrs Selley and two of their sons gave evidence to show that Mr Selley had had an accident

some years ago and had claimed compensation. Dr Rellum who had then been Dr Frelich's assistant had examined him and given him a certificate on which he had made good his claim. The family had been friendly with the respondent who had been chronically short of money and had frequently borrowed various sums from Mr Selley. On one occasion he had said that he must get as many patients as he could and had asked them to go on

his panel. They had refused except the youngest son. Mr and Mrs. Selley admitted that they knew that Dr Rellum was under a bond not to practise in the neighbourhood and that he had received a letter from the insurance committee saying that he could not visit patients in Bermondsey.

Without calling on the respondent, the Council decided that the charges had not been proved to its satisfaction.

REVIEWS AND NOTICES OF BOOKS

Diagnosis and Treatment of Arthritis

By RUSSELL L. CECIL, M.D. Sc.D. Professor of Clinical Medicine, Cornell University, London. Humphrey Milford, Oxford University Press. 1937. Pp. 263. 21s.

THIS is one of a series of monographs, edited by Dr H. A. Christian and written by leading authorities whose object is to bring to the practising physician a knowledge of the most approved methods for the diagnosis and treatment of disease. Dr Cecil whose investigations into the infective nature of acute rheumatism and rheumatoid arthritis are of recognised importance has written the volume on arthritis. At the outset he states—and few will differ from him—that there is no disease in the whole field of medicine in which purely symptomatic treatment leads to more barren results. The title is used to cover a wide field including rheumatic fever and certain of the less common forms of arthritis are unusually well described. Septic arthritis including gonococcal and staphylococcal and rarer forms, traumatic, syphilitic and tuberculous arthritis and intermittent hydrarthrosis among others are clearly differentiated. In view of the important researches carried out by the author himself into the bacteriology of rheumatic fever and rheumatoid arthritis it is natural that much space should be devoted to this aspect. The work of other investigators receives due consideration and the conclusion is reached that though the streptococcus is an important aetiological factor, the particular type of streptococcus involved is not yet settled. The findings appear to strengthen the view that mutation takes place between the different types. The author favours the use of streptococcal vaccine by the intravenous route in the treatment of rheumatoid arthritis but warns against overdosage which may cause a severe exacerbation of the disease. There is certainly a reaction against this form of treatment and any benefit that may accrue is now generally attributed to desensitisation rather than immunisation. Other methods of treatment are fully described together with useful systems of diet.

The section on gout adds nothing to common knowledge. It is curious that the British spas where gout has been successfully treated for centuries are not mentioned whereas certain continental spas of less importance in this respect are approved. The section on spondylitis is scanty—the so-called von Bechterew type is regarded as the osteoarthritic form which is not the view held by most of those who have referred to von Bechterew's original description.

The book is well got up and the illustrations are good. It will be found a useful and practical guide to the management of a common but difficult group of diseases and though it is sketchy in parts a very full list of references is supplied.

Early Science in Cambridge

By R. T. GUTHRIE, M.A. Hon. LL.D. Curator of the Oxford Museum of the History of Science, Oxford. Published by the author at the Old Ashmolean, Oxford, 1937. Pp. 513. 42s.

DR GUTHRIE has earned everyone's gratitude by what he has done for the Old Ashmolean Museum and for the series of books on early science in Oxford which he has published. He now turns his attention to Cambridge. His work is not a formal history but as he says more a series of notes centring round a list of surviving instruments which have been associated with teaching and research in Cambridge many of which were shown at an exhibition in the Old Schools in 1936. It is full of interest and if we fail to find something which we might expect we come across a great deal which is surprising. How those who discuss the curriculum must envy the education which William Stukeley got about 1703. We hunted after butterflies, dissected frogs, used to have set meetings at our chambers to confer about our studies, try chymical experiments, cut up dogs, cats and the like. A small wonder that when he reached the dignity of Goulstonian lecturer he had risen to dissecting an elephant. Or read of the wise royalist Dr Bowles who having to treat for a dysentery a roundhead captain who had been tearing up prayer books, cured his patient by a decoction of the prayers for the visitation of the sick from the defiled volumes boiled in milk. No very clear distinction seems to be made between work done in Cambridge and work done elsewhere by Cambridge men and there are we suspect a fair number of small inaccuracies but we can heartily commend the book for casual reading. It will probably incite many journeys to Cambridge to see such things as Charles Darwin's red handkerchief draped over the microscope he used to use and to residents will no doubt be quite a revelation.

Milk Products

By W. CLYDE HARVEY, M.D. D.P.H. Medical Officer of Health, Southgate and H. HILL, Sanitary Inspector, Southgate, London. H. K. Lewis and Co. 1937. Pp. 387. 16s.

THE milk products described are ice-cream, cream, butter and margarine, cheese, condensed milk, evaporated milk, dried milk, and some subsidiary milk products such as fermented milks and malted milk. The subjects are dealt with on a regular orderly plan which is convenient and easy to follow: a definition, food value, bacterial content and their sources, manufacture, any diseases transmitted by the particular food, chemical composition, bacteriological and chemical examination, legal position and where appropriate any legal or recognised standards. The balance between these different sections is for the most part, well maintained. Ice-cream is fully

discussed—this chapter occupies 84 pages—while evaporated milk might have been given a little more space. Very little of importance is omitted but no mention is made of staphylococcus food poisoning in connexion with cream filled pastry, a matter of increasing importance. No colour tests are given for the presence of vitamins added to margarine, indeed, the chemical examination of margarine seems to be omitted. The difficulty of making a satisfactory injection emulsion for examining cheese for tubercle bacilli is not dealt with. Under the heading sweetened condensed milk the hydrometer is given as the only instrument whereby the progress of concentration can be determined, the use of a viscometer is not mentioned. Emphasis might have been given to the importance of the retainer in connexion with the moisture and bacterial content of dried milk.

Much of the information given is not readily accessible elsewhere and the authors have done a considerable service in making it available in this well written and convenient form.

Hospital Law Notes

By W E C BAYNES, M A, LL M, Barrister at Law. London. Joint Council of the Order of St John and the British Red Cross Society 1937. Pp 93 5s.

Mr Baynes, who is honorary legal adviser to the British Hospitals Association, has found that the same questions are repeatedly put to him by secretaries of voluntary hospitals. He has therefore collected for publication the notes on points of law which form the substance of his replies. They cover almost every conceivable legal or semi legal difficulty which a hospital secretary is likely to encounter. There is an adequate index and footnote references are given to the principal leading cases. The allusions to the National Health Insurance Act of 1924 need to be adjusted to the consolidating statute of 1936. Similarly in the note on infectious diseases the references on pp 21 and 22 to the public health enactments of 1875 and 1925 and the Infectious Disease (Notification) Act of 1889 will need to be replaced next October by references to the equivalent provisions of the big new Public Health Act, 1936, which Mr Baynes cites at p 55 as if already in force. These, of course, are minor points, the law is accurately stated but the statutes where it is now to be found have been rewritten in the past twelve months. The notes on road accident patients, on the recovery of income tax under subscribers' seven year covenants and on liability for negligence are good instances of the clear and concise help which Mr Baynes offers to his readers. The secretaries of hospitals and similar institutions who buy his little book will get good value.

War Dance

A Study of the Psychology of War By E GRAHAM HOWE, M B, B S Lond, D P M London. Faber and Faber 1937. Pp 315 7s 6d.

It is no indictment of Dr Graham Howe's work to state that his thesis is a search for a mystical solution of the problems of human behaviour. War represents one of the types of disharmony which can, he holds, be overcome by the same methods which he has attempted to expound in earlier books ("I and Me," and "Morality and Reality")—i.e., by a resolution of the antinomies in the self—the duality of inner and outer, private and public, cognitive and conative thinking and spontaneous living. Dr Howe enjoys

similes and aphorisms (some penetrating, others singularly impenetrable) carrying the reader along in a pleasant flow of bright ideas and dark sayings. But as one reads on, it seems that one has not progressed in a stream, but raced in a whirlpool. Dr Howe has been unwise, perhaps, to invoke the Fourth Dimension. Of course, if we could be in all dimensions at once, woefully as we are tied to three (and quite incapable of living in one or two) reality would certainly be revealed to us. But here we must use mathematical notation and not surrealist (polite variety) drawings which do not, for most people, clarify the issues. Dr Howe would have succeeded better, indeed perhaps brilliantly, if he had chosen another title. For he has said little about war and the reader is left with the impression that "c'est magnifique, mais ce n'est pas la guerre."

British Journal of Children's Diseases

(Vol. XXXIV, April-June).—In an article on Epidemic Myalgia in Children, Dr W N Pickles reviews the literature and records his experience of an outbreak of 31 cases which occurred in Wensleydale, Yorkshire, in the summer of 1933, 15 were in children under 11 years of age, 15 in young adults, and one in a man of 52. His conclusions are as follows. The disease appears to spread by direct contact, and the incubation period is short, ranging from two to four days. The period of infectivity continues during the course of the disease which is also short. There is no evidence that the disease is conveyed by food, water, or animal vectors. It occurs mainly in the late summer and autumn. One attack does not confer immunity. The chief importance of the disease which has good prognosis is its tendency to simulate serious conditions such as acute pneumonia and acute abdominal emergencies, especially appendicitis and intussusception. In his paper on Morbilli Bullosi Dr G W Ronaldson, who records two personal cases, one in a girl aged 4 years who recovered, and another in a female infant of 10 months who died, illustrates the rarity of this condition by the fact that they were the only examples of morbilli bullosi in a series of 4362 cases of measles admitted to the South Eastern Fever Hospital in the period 1930-36. Ronaldson maintains that morbilli bullosi should be defined as a variety of the measles exanthem and not as a distinct variety of the disease. He classifies the reported cases into one or other of the following three groups: (1) cases in which a bullous eruption was associated with a morbilliform erythema, (2) well-authenticated measles with an eruption which had pemphigoid elements, of which his two cases were examples, and (3) cases of measles in which a bullous eruption followed the true rash either immediately or after varying intervals.—Dr E F Dawson Walker and Dr E G Brewis contribute a paper on Two Unusual Cases of Diphtheria. The first was a case of a severe naso-pharyngeal form of the disease in a female infant aged 9 days. Recovery followed two intramuscular injections of antitoxin. Nasal and faucial swabs showed *C. diphtheriae* of the intermediate type. The second case was that of a boy 12 years old who developed chorea in the course of characteristic diphtheritic paralysis, and recovered. Similar examples of this very rare complication of diphtheria have been recorded by Globus (1923), Critchley (1921), and Mühlentkamp (1934).—Dr D MacIntyre and Dr H L W Beach report a case of Acute Encephalomyelitis Complicating Chicken Pox. The patient was a girl aged 7 years, in whom the complication developed on the twelfth day of an attack of chicken pox. Complete recovery took place without any special treatment in the course of three months, and when seen about eight months after discharge from hospital the child showed no sign of mental or physical weakness.—The abstracts from current literature are devoted to acute infectious diseases.

THE LANCET

LONDON SATURDAY JUNE 12 1937

WAGES AND HEALTH

THE prospect of a declining population was recently reviewed in our columns¹. It may be as some of the writers on the subject contend, that the low and falling net reproduction rate arises rather from psychological than economic causes. Nevertheless those who live below the margin of subsistence have a specially good reason to make increasing use of the contraceptive measures now at their disposal and so accelerate the fall. Science has given the poverty stricken a practical answer to the assumption that their continuance in that state is inevitable if regrettable feature of the social system. They can now die out of their own volition. Whether the prospect of a falling and ageing population is a matter for alarm or not, there are students of economics who maintain that there is no reason why the extreme forms of its economic origins should continue. Mr SELWYN ROWNTREE has recently rewritten his book first published in 1918 on the Human Needs of Labour - His basic facts are derived from a survey of 2875 completed families in the town of York - families completed in the sense that the mother was aged 40 to 45 years at the date of the 1931 census. He has been able to trace the number of dependants in different sizes of family from year to year since the eldest child was born. It gives reason for believing that York is a fair sample of the country, but admits that his investigation is too small to yield absolutely conclusive results. Of these families 17.7 per cent had no children, 25.1 had had a maximum of one child, 24.2 two children and 14.7 three children simultaneously dependent at some time, the percentages rapidly diminishing for larger maximum dependents. The percentages of children in the families arranged in the same order of classification but excluding the childless families were 34 for one child, 24.02 for two children, 21.03 for three children and so on dependent at any one time.

Mr Rowntree's line of inquiry is designed to explore the problem of a living wage and it shows that if such a bare minimum were to be based on the needs of families with children only, 63.6 per cent of the children of fathers receiving it would be inadequately provided for at some time and 68.8 per cent would be in that condition for five years or longer. Even the minimum wage were determined on the needs of families with three children, 42 per cent of children of all sizes would be inadequately provided for over varying

periods, and 34.5 per cent for five years or more. In his view a minimum wage is necessary and practicable. It should be fixed on the needs of a man, woman and three children, the requirements of larger families at low income levels being met by the admittedly difficult provision of State family allowances. In endeavouring to determine such a wage he uses average retail and other prices of his own ascertainment applied to the estimated needs of a family of five persons. As regards food he has been guided by the dietaries contained in

Family Meals and Catering published by the British Medical Association giving 3400 calories per man for a family equivalent to 3.76 adult males. In this way he builds up a minimum wage of 53s per week, including 20s 6d for food, 9s 6d for rent, 8s for clothing, 4s 4d for fuel and light, 1s 8d for household sundries and 9s for personal sundries. Mr Rowntree has been publicly criticised by the Children's Minimum Council² for the meagreness of his dietary but he has been careful to state that he has deliberately erred on the side of stringency rather than extravagance, that even this wage (or its equivalent of 41s in the case of agricultural workers) would be a great advance on anything earned by a large proportion of workers at the present time, and that his experience on a trade board leads him to believe that its gradual but reasonably rapid application to all industries would have no crippling results. He is aiming at the bare subsistence necessary for health and well being not at an income above the level of which they could not be improved.

If this minimum income of £137 10s per annum for industrial workers is accepted it would be important to know how many families are maintained below this level. Thus, unfortunately, it appears to be impossible to ascertain with anything approaching accuracy. A general impression, however, may be gained from official figures and from estimates made by various writers. In their latest book³ G. D. H. and M. I. COLE paint a picture of our society on a much wider canvas than Mr Rowntree's, bringing together data gathered by experts about national and class incomes, nutrition, housing, unemployment, education, standards of life, social services, taxation, production and the past and prospective struggles of working men for better conditions. The facts are as near the truth as the available methods of scientific investigation permit whatever may be our view of the remedies proposed by the writers. In May 1936 there were nearly one and a half million males unemployed of whom more than one million were over 25 years of age. Some of these were certainly unmarried and many at such an age that their families had ceased to be necessarily dependent, but it is well known that a large number have a wife and three or more young children to maintain. Unemployment benefit for such a family is at the rate of about £78 a year for the chronic unemployed who come under the Public

¹ *Lancet*, April 11th 1937, 233, 911.
² London: Longman, Green and Co., 1937, 162, 2s. 6d.

³ *The Condition of Britain*, May 1937, 1st 4s. 6d., 2nd 7s. 6d. London: Victor Gollancz, 1937.

Assistance Board it may be higher according to circumstances but, in any case, usually it is less than £100. When to those groups are added the families who are entirely dependent upon local poor-law assistance, usually at comparable rates, it is evident that many of the non earning families in the community have far less to live on for prolonged periods than the estimated subsistence wage. As to those who are earning, it appears from estimates of COLIN CLARK, quoted by the COLES, that more than 60 per cent of the national incomes in 1929 (i.e., before the financial crisis) were below £125 per annum and, indeed, that the average of all incomes was below £200 per annum. It should be remembered that more than one income may be represented by one family, there are, in fact, more than twice as many incomes as there are families. Nevertheless, it is clear that many young families dependent on a single wage earner must fall into the lower earning categories. Knowledge of local families and their wages indicates that this is the case.

If, then, scientific work on nutrition and the inquiries into the costs of commodities are anywhere near the mark, the volume of those who are inadequately fed must be large. The Government has recognised this position by urging local authorities to make fuller use of their powers to provide free or cheap meals and milk for children, and for expectant and nursing mothers. In recent years the urgent need for an outlet for the surplus production of agriculture has provided a new incentive to the governments of all countries represented at Geneva to arrive at an international policy which will increase the consumption of food. In the meantime, there is scope for further intensive inquiries into local family incomes, such as those included in the London and Merseyside surveys and in MCGONIGLE'S investigations at Stockton. Possibly the survey to be carried out by the Ministry of Labour in connexion with the cost of living will afford information covering a wider range of the population than any data at present available. The needs of people can only be estimated roughly but actual incomes should be ascertainable with a reasonable measure of precision.

BATHING AND THE EARS

As summer weather has now happily arrived, we may expect the usual crop of ear troubles due to bathing. Man is not an aquatic animal and, unlike many mammals that have reverted to a life in the water, he has no mechanism for closing the auditory meatus or the nostrils, hence water can reach his ear either through the meatus or through the Eustachian tube, though harm is rare in proportion to the number of bathers. Water easily gets into the meatus during swimming and produces a disagreeable sensation, but it soon runs out again from an unobstructed canal. If, however, there is any considerable quantity of wax, this imbibes the water, swells, and obstructs the passage so that the sensation of water in the ear, persisting long enough to cause the sufferer to seek advice, is nearly always caused by

cerumen and cured by its removal. Those who secrete much wax should have it removed before the bathing season. This retention of moisture readily leads to a dermatitis and is the usual cause of external otitis resulting from bathing. Apart from the presence of wax, those with a tendency to eczema are apt to suffer an exacerbation from bathing, such people should wear an efficient plug and dry the ears carefully afterwards, they may with advantage insert a few drops of oil or of nitrate of mercury ointment (1 drachm to an ounce of equal parts of olive oil and liquid paraffin). In some tropical regions, a very severe form of external otitis is a common complication of bathing apparently caused by minute larval forms of marine organism, "Bombay ear" and "Singapore ear" are well-known examples.

Much more important than external otitis is the middle ear suppuration that may result from bathing. One important cause of this is the entrance of water through an old quiescent perforation of the drum—an event liable to be followed by very severe suppurative otitis and the danger of serious complications. Patients with an open perforation should never bathe without using really efficient means for preventing the entry of water into the ear. A plugging material, made of a mixture of animal wool and plasticine or wax, is obtainable at chemists and is satisfactory if intelligently applied but ordinary cotton wool is worse than useless since it only gives a false sense of security, a rubber bathing cap to cover the ears should be worn over any plug. Unfortunately, people with perfectly healthy ears, too, may get acute otitis media after bathing, owing to the entrance of water into the tympanum through the Eustachian tube. This occurrence is assisted by swallowing and, more frequently and particularly, by forcibly blowing the nose while the nasal passage is still full of water. If the public could but be taught to refrain from blowing the nose until the water has drained out of it, otitis media after bathing would become rare. Patients with otitis from bathing very often give a history of a sudden crack and pain in the ear on blowing the nose, followed soon by earache. The ear is peculiarly susceptible to infection by micro organisms as introduced, and although of late much care has been devoted to the purification of swimmingpools and baths, these may play an important part in the spread of streptococcal infections when, in a school, such diseases as rhinitis and tonsitis are present. Epidemics of nasal sinusitis have also had a similar origin. But infection of the bathing water is not an essential condition for organisms from the patient's own throat or nose may be carried with the water along the Eustachian tube. Otitis media from this cause is naturally more likely during an attack of coryza or sore throat and bathing should be avoided by people thus afflicted.

In conclusion, may be said that when the external meatus and drum is healthy, plugging the canal is unnecessary except to prevent direct damage in high diving. The subject of a perforated drum runs a substantial risk from the entry of

water and must be very careful to exclude thus if he bathes at all. A healthy drum can only be infected through the Eustachian tube and this is unlikely if the bather refrains from swallowing while in the water and, especially, from blowing the nose on coming out and if he does not bathe while he has a cold or a sore throat

ELEMENTS OF POPULATION

IF the predictions of both amateur and professional soothsayers are even reasonably near the truth the future of our population is a question likely to remain in the public eye for quite a long time. The basis of these predictions is of course the present level of fertility and mortality with various adjustments made to each according to the worker's idea of what may happen to those rates in years to come. One and all are agreed that (apart from immigration) our population must within a few years begin to decline and unless there is a considerable increase in the birth rate to decline at an accelerating rate. And so the question arises as to whether anything can be done to check a further decline in fertility whether with the aid of a Royal Commission the urge to contraception cannot be stayed. Most but by no means all competent observers believe that the fall in fertility is mainly if not entirely due to deliberate control of the size of family. But clearly contraception is only a means to an end and it is the basic causes that lead to the adoption of the means that we want to know more about. It seems a far cry from Royal Commissions and planned families to fruit flies and flour beetles but as RAYMOND PEARL, a pioneer of the experimental approach in this field has recently emphasised¹ the fundamental problems of population are biological problems. What for instance is it that makes populations slow up in their growth rate and approach ever nearer to a limiting size which they never quite reach? What is the explanation of the phenomenon of periodic rapid multiplication of populations of lower mammals of which lemmings are the classic example? Are there laws of population growth by which man as well as the lower animals are bound so that the best laid schemes of committees can have little effect upon his development? The sociologist the experimental biologist and the ecologist must play their part in solving such problems none of them can succeed in doing so alone.

The experimental method has already given results of much interest. For instance several studies suggest that groups of insects survive the effects of various environmental poisons more easily than do isolated individuals. These have shown that morphological changes may take place under certain conditions of crowding. The factor which has had most attention paid to it is density and a very interesting discussion of its influence has been published² by Dr THOMAS PARK of the department of biology of the school of hygiene and public health Johns Hopkins

University. PEARL's work on *Drosophila* is well known, it shows the inability of this fly to oviposit and feed adequately when disturbed and this provides evidence that population density may alter the behaviour of its components. Less familiar perhaps are the experiments which PARK quotes of various workers with *Tribolium confusum* a beetle which spends its entire life cycle in flour. Here also a limiting size to the population in relation to its environment has been observed. These beetles eat their own eggs and this cannibalism varies directly with the number of eggs and imagoes present so that when the concentration of the latter is high the rate of cannibalism is high. Also, flour in which dense populations of *tribolium* have lived has its nutritive value reduced and is affected by the addition of excretory and metabolic wastes. It has been shown that beetles living in this conditioned flour have their fecundity drastically lowered and their larval mortality increased. It thus seems that an environmental modification takes place which is a result of the activity of the population itself and this modification plays an important part in guiding the course of the *tribolium* population. PARK also quotes the work of MACLAGAN and DUNN³ on the grain weevil *sitophilus* which shows decreased fecundity with increasing density, which seems to be due, as with *Drosophila*, to reduction of the times available for feeding ovipositing and resting, which caused adverse effects upon the physiological processes of reproduction.

Such studies as these are still adding to the little we still know of insect populations and the underlying principles of their growth. Of mankind we know perhaps even less. PEARL's interpretation of the scanty data seems the most reasonable—that for thousands of years the human population of the earth grew slowly till some 300 years ago the development of scientific discovery (including exploration as well as technology) suddenly expanded man's effective universe and has kept on expanding it. There has followed a spurt of population growth of an explosiveness that is seen when plotted to a proper time scale to be comparable to that of an epidemic. This history PEARL compares with what we know of the lemming. The essential biological elements he suggests are these: first a population relatively constant or very slowly growing as a consequence of the operation of natural check; secondly during a relatively short period on the total time scale of the species these checks are abated and a large expansion results; thirdly the increasing density leads to disturbance reactions and lastly these reactions lead to undirected mass migratory movements and ultimate destruction of major parts of the population. Up to a point there seems to be a parallelism in the history of mankind. Unrest is a dominant characteristic of human behaviour to-day perhaps a symptom of discomfort associated with density. Not being a prophet PEARL does not envisage mankind

¹ Amer. Nat. 1933 71 50
1934 1

² Proc Roy Soc Edinb 1935 58 126

marching to a watery grave just behind a horde of frantic lemmings. But does anyone," he asks, "find it difficult to conceive of man marching off in the not too distant future to a war? Or to doubt that, once well started, that war will entangle in its meshes the major portion of mankind before it is finished? Or, finally, to doubt that the next world war will achieve a destructive-

ness hitherto undreamed of in the wildest flight of imagination?" The thought is not a cheerful one, perhaps, as PEARL admits, it is essentially false. But the problems of population are difficult and serious, nothing but good can come of each form of attack upon them while general discussions such as PEARL has published merit thought and attention.

ANNOTATIONS

THE CAPITATION FEE AWARD

THE court of inquiry into the insurance capitation fee met at the Ministry of Health on four successive days from May 26th to 29th when Dr H Guy Dam presented the case for the Insurance Acts Committee of the British Medical Association and Mr T D Harrison presented the case of the Ministry of Health and of the Scottish Department of Health. The Medical Practitioners' Union and the Joint Conference of Friendly Societies also gave evidence. At the conclusion of the inquiry Lord Amulree, the chairman, expressed the court's high appreciation of the cases which had been presented so fairly by the parties concerned and added the hope that the decision the court would presently announce would give satisfaction. After an interval of a week the finding of the court was published on Monday last to the effect that the appropriate capitation fee should remain 9s the figure applying both to insured persons over the age of 16 and to employed adolescents under 16 when they become legally entitled to medical benefit. The Minister of Health in making the announcement adds that the introduction of legislation to entitle boys and girls to medical benefit immediately on becoming employed (on reaching the school leaving age) has awaited this decision. It will now be possible to introduce the necessary Bill.

VARICELLISATION

ALTHOUGH a mild disease, chicken pox is a troublesome one, especially in children's wards and schools, for it is very infectious, has a long incubation period, and may take a long time to heal completely. Satisfactory means of prophylaxis are still to seek, isolation and quarantine, however prompt, are seldom wholly successful if the susceptible contacts are young. Specific prophylaxis by injection of the pooled serum of convalescents has had very equivocal success, the age groups of the children exposed, the degree of exposure and especially the variability of the antibody content of the samples of serum which composed the pool may account for the failure of one experiment or the apparent success of another. The suggestion of Amies¹ that by means of agglutination reactions it may be possible to select sera of high antibody content instead of pooling samples of unknown titre may form a sound basis for future work. Lastly there is varicellisation, the counterpart of variolation and its contemporary since, as I D Rolleston,² points out it was first employed by William Heberden the Elder in 1767. Rolleston remarks that "in striking contrast with small pox, the results of the inoculation of chicken pox have been remarkably inconstant. Willan was unsuccessful at the beginning of the nineteenth century. Steiner, however, seventy years later was more fortunate

and since then occasional successes have been reported by other workers." Some of these are mentioned by Prof J W Bigger,³ who gives details of the apparently successful varicellisation of his daughter by means of the intradermal injection of the contents of vesicles derived from his son. During the 48 hours before the appearance of the boy's eruption (and therefore during the most infective phase of chicken pox) the young adult sister had been in close contact with the school boy brother. One insertion was made into the girl's forearm, of the fluid—a minute quantity—collected from five vesicles and suspended in saline. On the eighth day after inoculation the site was slightly red, next day a definite papule was present, and 24 hours later this had become a vesicle indistinguishable from a lesion of chicken pox. There was no pyrexia or constitutional disturbance, the local lesion disappeared in a few days, and no generalisation took place. As to the duration of immunity Dr Bigger expresses no opinion, but it may be said that in some at least of the recorded examples immunity was temporary, although the clinical attack following a subsequent exposure was mild. It is clear in any case that the method, like the long abandoned variolation, is unsafe for general employment, familial protection is another matter. Dr Bigger's only anxiety was, he says, the possibility of producing herpes zoster. The intradermal inoculation employed by him appears preferable to the puncture or scratch insertions used by others.

NUTRITION AND INFECTION

IN reviewing the latest report of the Foot and Mouth Disease Research Committee (p 1290) we remarked that the by products of the research done have a value of their own. One of these by products, which requires further analysis, is the observation by Mr J T Edwards, D Sc, that well nourished rats can be infected with foot and mouth disease more readily than those that are ill fed.⁴ Early workers at the Lister Institute and elsewhere had found that young guinea pigs, and those in a poor state of nutrition, are more liable than others to resist this infection, and since 1932 experiments have been done at the Lister Institute and the Pirbright Experimental Station to decide how far these differences of reaction are due to nutrition and how far to size, age, race, or to other conditions. Rats were used for most of the experiments because they are not easily upset by changes of food. They were divided into groups and each group was inoculated intradermally with virus after a period on a particular diet. The two factors found to influence susceptibility and severity of illness were age and nutritional state. Very young and very old animals and those

³ Bigger J W. *Irish J med Sci* March 1937 p 126.

⁴ This observation was mentioned by Dr Edwards at a sectional meeting of the Royal Society of Medicine reported in our issue of April 3rd p 811. Details are given in the Committee's report (pp 190-223).

¹ Amies C R (1933) *Lancet* 1 1015.

² Rolleston J D (1937) History of the Acute Exanthemata, London.

which were ill nourished were relatively insusceptible—a finding which applied, though less definitely to guinea pigs and hedge hogs as well as to rats. A third factor which lessened susceptibility was concurrent infection possibly by lowering the general state of nutrition. Whether any one component of the diet is especially concerned was not determined, but it was noted that addition of raw liver appeared to increase susceptibility within a few days. If the rats then went back to a less nutritious diet it was more than three months before they lost their abnormal susceptibility to inoculation—a finding that could be explained by suggesting that a pro infective factor in the liver was stored in the animal. The decreased susceptibility of the rats on an inadequate diet was found to be associated with the presence of a definite anaemia and the addition of liver to the diet may have acted by correcting this. Whether these observations apply to farm animals has not been investigated, but Dr Edwards gives a chart showing that in India foot-and-mouth disease in cattle is commonest at the time of year when fodder is plentiful and the animals are in prime condition and is comparatively rare in the hot weather when they are often grossly undernourished.

OPIMUM SMOKING IN THE FAR EAST

ON April 22nd what is known as the Bangkok Agreement on the Suppression of Opium Smoking in the Far East became effective and another stage was reached in the effort to control or restrict narcotic addiction by inhalation. By the Hague Opium Convention of 1912 the contracting powers engaged to take measures for the gradual and effective suppression of the manufacture of internal trade in and use of prepared opium—i.e. opium to be used for smoking. They also undertook to prohibit the import and export of prepared opium, moreover those powers which were not then ready immediately to prohibit such export undertook to do so as soon as possible. Little however was done in this direction and indeed the Geneva Conference of 1925 having registered the opinion that smuggling in the Far East hampered effective suppression as had been contemplated agreed by protocol to postpone the measures undertaken in 1912 until a period of not more than 15 years from a date by which the obstacle referred to had been removed. A commission of three visited the Far East and reported in 1931 to a conference at Bangkok on the situation as then disclosed. The agreement then arrived at provided for the retailing and distribution of opium for smoking to take place only from Government shops or under Government supervision. Smoking under 21 years of age is prohibited and prepared opium may be sold by the Government monopolies for cash only. Licensing, rationing or registration of smokers is provided for. Penalties for offences are prescribed and provision is made for research as to the effects of opium-smoking and means to facilitate its cure. Reports are to be made annually to the League of Nations and a special opium revenue account is to be kept.

The agreement which has now come into force has been ratified by all the Governments parties to it—viz. the United Kingdom for the Malay States and Hong Kong, Burma, the Netherlands for the Netherlands Indies, France for Indo China, Siam, Portugal for Macao and Japan for Formosa and Kwantung. It will be remembered that the commission of inquiry felt that opium smoking could not be dealt with apart from opium-eating and recorded their opinion

that the radical method of dealing with illicit traffic in opium is by controlling effectively the cultivation of the poppy. This fundamental question of the limitation of the production of the raw materials is now at long last, under instruction of the Council and Assembly engaging the attention of the League of Nations.

THE PHARMACEUTICAL SOCIETY'S NEW HOUSE

THE Council of the Pharmaceutical Society has approved the architect's plans of a new building for the society's headquarters. The site which has been acquired has a main frontage in Brunswick-square of 237 feet and a minor frontage in Hunter-street of 113 feet. The architect is Mr Herbert J. Rouse of Liverpool, he built Martin's Bank Building in that city and other edifices which have attracted admiration. The structure provides six floors of accommodation above the street level with general service rooms of all kinds in a basement. By the use of separating courts for light, three wings are provided each enjoying a maximum light exposure on three of their sides. The plans of the third, fourth and fifth floors show that continuous depths of laboratory accommodation are provided along the whole length of the front served by corridors lighted from the courts. The school of pharmacy occupies the whole of the third and fourth floors together with the portions of the ground first and second floors which make up the east wing of the building. The fifth floor is utilised for pharmacology including a nutrition department. The assembly hall, library and main lecture theatre occupy the centre of the ground and first floors and the council suite is placed centrally on the second level. On the ground floor a lofty vestibule at the entrance is flanked on the right and the left by the assembly hall and library respectively while directly facing the vestibule is a lecture theatre to seat 250 persons. The assembly hall itself extends over the height of two ordinary floors and will seat 400 persons. The library is also a room of two floors in height and is planned with bays in which are placed small tables for reading. The west wing is devoted to the publications and editorial department. The estimated cost of the building is £200,000.

CONDITIONED DEFICIENCY DISEASE IN ANIMALS

IT is now known that man may suffer from many deficiency diseases even when his diet is in every way adequate. The fault lies in defective gastro-intestinal function which prevents the use of the food by the body—in other words there is a conditioned deficiency. In Addisonian pernicious anaemia lack of the haemo-poietic principle is due to a failure on the part of the stomach to secrete the intrinsic factor. In hook worm anaemia though the diet is often deficient the presence of parasites is held by some to play some part in preventing the proper utilisation of iron. Important studies of a wasting disease in sheep known as Border pining recently made by W. J. Stewart and his colleagues suggest that this may also be a conditioned deficiency disease due to parasites. That pining was in some way due to diet was suggested as long ago as 1831 by James Hogg the Ettrick shepherd because he found that it was improved by changing the pasture. Since its most characteristic feature was a severe anaemia it was formerly considered that it was due to a lack of

¹ Stewart W. J. and Merry E. S. (1933) *J. comp. Path.* 43, 137.

iron in certain pastures. It was found that iron content of pastures was on the whole lower in pining areas than elsewhere. On the other hand, in the Border country at least, the provision of iron containing licks for sheep has not been effective in preventing the disease. Stewart and his colleagues therefore undertook a further study,² of the condition and have made interesting observations. The constant symptoms are emaciation and an anæmia that appears to be normocytic in type, both red cells and hæmoglobin being equally affected. This might in itself suggest that lack of iron alone is not the cause of the disease since simple iron deficiency anæmia is usually hypochromic. Examination of the faeces showed a higher proportion of ova in pining sheep than in normal controls, and the egg index varied inversely with the severity of the disease and the intensity of the anæmia. Nematode parasites were found post mortem in the stomach and intestines of all sheep examined, the largest number being present in animals seen during the summer, when pining is at its worst. In 13 cases there was damage to the gastric mucosa, the typical lesion being a thickening and roughening of the membrane. Stewart believes that the sheep surviving a summer attack of pining remain in poor condition and often die of malnutrition and broncho pneumonia during the winter. At this stage the parasites may be few and post mortem examination may fail to give conclusive evidence of the important part they play. This disease at once suggests a possible analogy with hookworm anæmia in man. Damage caused to the stomach and intestines by the parasite, of which Stewart has found histological evidence in the sheep, may result in deficient absorption of iron especially if the amount in the diet is low.

HÆMOPHILIA RECORDS

The clinical history and description of 98 patients suffering from hæmophilia, with a series of 75 pedigree charts, forms the text of a monograph recently published by Dr Carroll Birch.³ It would be difficult to overestimate its value. It supplies such details of a unique series of unselected cases, personally examined, as enable the reader to get an idea of the case to case variations in the course of the disease and of the accidents to which individual sufferers may be subject. Particulars of 113 cases of death in hæmophiles are given, showing that no fewer than 57 per cent of the persons affected died during the first five years of life. Dr Birch finds no uniformity in the variation in the severity of the disease at different periods of life, some patients appear to have more severe and more frequent hæmorrhages as they grow older, of others the converse was reported. Many factors may contribute to fluctuation in the severity of the disease at various periods during life. The pedigree charts will be welcome to geneticists, only those who have attempted the investigation of family histories can fully appreciate the labour involved in this section of the monograph. Pedigrees worked out as a routine measure, in every case of a disease seen, have not only their own particular interest but reveal much about the genetical character of a condition which can only be discovered from material collected in this way. Discussing the occurrence of hæmophilia and colour blindness in different members of the same family, Dr Birch

writes that the combination of these two anomalies in one male is theoretically impossible. Geneticists are likely to question this statement—indeed, several pedigrees have been recently published which demonstrate a very close linkage between the two conditions in certain families.

Good pictures and diagrams illustrate this monograph and Dr Birch deserves thanks for a valuable contribution to the subject of hæmophilia.

PLANTAIN HAY-FEVER

In a group of 180 sufferers from hay fever Blumstein and Tuft¹ found 14 (7.7 per cent) who were sensitive to plantain pollen, and among 70 cases of spring hay fever there were 5 in which plantains appeared to be the sole exciting cause. The observations recorded suggest that the "English" narrow leaved and the "common" broad leaved plantain—the lesser and the greater plantain respectively—contain a common antigenic factor quite distinct from that found in Timothy grass or ragweed. The dry pollen nasal test was found to be an invaluable aid to the diagnosis of plantain hay fever and Blumstein and Tuft believe that intractable cases of spring hay fever will often yield to treatment if plantain extract is included in the injections of grass pollen extracts.

THE RISE OF THE TUBERCULOSIS DISPENSARY

Fifty years ago a young graduate started in three small rooms at 13, Bank street, Edinburgh, the Victoria Dispensary for Consumption. When he founded it Dr Robert Philp, as he then was, probably did not himself realise what a world wide development of the antituberculosis organisation he had inaugurated. There are times in the history of most movements when an entirely new idea is conceived and progress is rapid, and there are times when the movement settles on its lees and becomes stagnant. The years 1882 to 1887 were a turning point in the history of the fight against tuberculosis, and Sir Robert Philp, looking back upon it after fifty years, may well be proud of his share in it. The period which preceded it marks the growth of the special voluntary hospitals. Beginning with the foundation of the Royal Chest Hospital in 1814, some sixteen hospitals for tuberculous diseases had been founded in the British Isles by the time the Victoria Dispensary saw the light. Some of them came into being for the purpose of helping the patient with advanced disease whose lot, with nothing but the old poor law infirmary to look forward to, was gloomy in the extreme, others, regrettably few in number, definitely set out to treat incipient consumption. But whether the early or the advanced case was the object the conception of the hospital was the sick person and him alone. The outstanding advance of the dispensary movement has been not merely the picture of a patient with physical signs but the realisation of the sick and infective person in his environment of home and community. From this time onwards there has been a new conception of tuberculosis, a chronic infective disease in its setting of family and immediate surroundings. And with this new conception came the idea of the contact and the search for the primary case in each family focus of infection.

Philp's ideas were only slowly followed up and Great Britain the country of its birth, had to

¹ Stewart, W. L. and Ponsford, A. P. (1936) *Ibid.* 49, 49.

wait until the report of the Astor Departmental Committee in 1912 before the dream of its founder was realised. Flick has pointed out that the period of voluntary hospital development in this country saw a marked decline in tuberculosis mortality. In 1848 the death rate was 2.07 per 1000 living; in 1888 it had fallen to 1.54. Now it has been nearly halved again and although these declines in mortality cannot be attributed to any one agency there can be no doubt whatever that the dispensary movement has justified the faith of its founder.¹

IN DEFENCE OF RESEARCH

Prof. G. Grey Turner, professor of surgery in the University of London at the British Postgraduate Medical School, who has recently been elected a vice-president of the Research Defence Society, will deliver the eleventh Stephen Paget memorial lecture at the annual general meeting of the society which is being held on Tuesday, June 15th at 3 P.M. at the London School of Hygiene and Tropical Medicine, Keppel-street, W.C. Prof. Grey Turner will speak on what research owes to the Paget tradition and the chair will be taken by Lord Lamington, president of the society, who will be supported by Sir Arthur Stanley and Prof. A. V. Hill, F.R.S. Members are invited to bring their friends to the meeting. The society may be addressed at 11 Chandos-street, Cavendish-square, London W.1.

INDUCTION AS A ROUTINE

Mathieu and Holman² of Portland, Oregon, compare the results in some 750 consecutive cases in which premature labour was induced, with those in another 750 contemporary cases in which the onset of labour was left to Nature. A study of these two series should (but may not) leave the reader convinced that no woman ought to be allowed to go into labour spontaneously. In the series in which induction was performed, the maternal mortality (one death) was half what it was in the other group while the fetal mortality (corrected) was in the same proportion. The length of the first stage of labour was considerably diminished in the induced series and there was no difference in the morbidity rate. The method of induction used is said to have been completely successful. At 7 A.M. an enema is given followed at 7.30 by a variable dose of pentobarbital. The patient is asleep in half an hour, and pituitary extract in 3 minute doses is injected at half hour intervals afterwards. If labour has not started after the third or fourth injection and the membranes are still intact, they are ruptured artificially. (It should be noted that this is not advised if there is a malpresentation or if the fetal head is not engaged.) The injections of pituitary extract are then continued until the patient is definitely in labour. In Mathieu and Holman's series there were no untoward results—no pituitary shock, no premature separation of the placenta, no precipitate labour—and it is somewhat ironical that the only case of rupture of the uterus was in the series of controls in whom labour was not induced. The indications for induction are stated most briefly as those cases which promised trouble: the toxæmia, large babies, contracted pelvic outlet, apprehensive and nervous patients, &c. The results seem to have been excellent yet we are not altogether

surprised that many of the speakers at a meeting to which they were related commented adversely upon the procedure and suggested that it is better to allow labour to start spontaneously unless there is some definite reason for the termination of pregnancy. Be this as it may, certain facts do demand careful attention. The method was employed over a large number of cases and the incidence of complications was negligible. Pituitary extract was used as a routine but in small repeated doses and its administration was stopped as soon as labour pains were established. There was no report of uterine inertia, and this is of interest in view of the attention lately drawn to the high incidence of inertia of the uterus in women in whom labour had been started by the insertion of bougies. The advisability of administering pituitary extract during induction of labour needs further examination.

PASTEURISATION AND THE NUTRITIVE VALUE OF MILK

The dangers of raw milk as a vehicle for the conveyance of disease are well known and repeatedly emphasised in our columns as well as the safety given by efficient pasteurisation. These are demonstrable facts that cannot be gainsaid, so the opponents of pasteurisation who fear its advent chiefly because of the disturbance they believe it will cause in present methods of distribution have to fall back on the argument that heat reduces the nutritive value of milk. They are apt to talk vaguely of the possible presence of some component that might be affected by pasteurisation but they cannot isolate or define it. A valuable report issued by the Milk Nutrition Committee³ provides no reason for thinking that milk contains any such factor and shows that there is little difference between the nutritive value of raw and pasteurised milk. Further evidence may be found in a report on the nutritive value of raw and pasteurised milk for calves by Prof. Wilson, Prof. Minett, and Mr. Carling.⁴ Their experiment, which lasted over two years, was made with milk from a healthy short-horn herd. Calves as they were born were allotted alternately without any selection into two groups: one fed on the raw milk and the other on the same milk after pasteurisation. Mixed morning milk was used and it was given in measured quantities in strict relation to the weight of the calves. This impartial allocation was not perfectly satisfactory and in fact operated against the pasteurised group because a fewer bull calves happened to be allocated to this group while it included two weaklings who died from other causes. Apart from these two all the animals thrived well and showed no signs of rickets or anæmia. The average increase in weight over the eight week period for the animals in the raw milk group (25 calves) was 53.72 lb. in the pasteurised milk group (23 calves) it was 53.80 lb. Incidentally the highest individual gain among the bull calves and also among the heifer calves was in an animal fed on pasteurised milk. No physical differences could be noted by any observers between the animals in the two groups. Prof. Wilson and his colleagues conclude that there is nothing in these results to suggest that the nutritive value of pasteurised milk for calves is in any way inferior to that of raw milk. Earlier studies have suggested that one effect of pasteurisation is to diminish the availability of the calcium and phosphorus in milk.

¹ A tribute is paid by the Edinburgh medical school to Sir Robert Philip's work in the *Edinburgh Medical Journal* for May 1937.

² Mathieu, C. and Holman, A. *Amer. J. Obstet. Gynec.* Feb. 1937, p. 65.

³ See *Lancet* May 11th 1937, p. 1179.
⁴ Wilson, O. S., Minett, F. C., and Carling, H. E. (1937) *J. Hyg.* 57, 213.

This could have no influence upon its nutritive utility for children, since the need of children for these minerals is less than that of calves, judging by the lower content of calcium and phosphorus in human milk. On the other hand, if the diminution were really substantial it would presumably affect the growing calf, and the fact that it did not do so—which surprised the investigators—makes it clear that this objection to pasteurisation of milk for growing children has no force behind it. Nor, in fact, have any of the other objections, and it is more than time that the medical profession, realising the importance of milk-borne infection, ranged itself solidly behind the demand for a safer supply.

E. L. EHLERS

THE three diseases with which the name of Prof Ehlers is most closely associated are syphilis, leprosy, and scabies. He was president of the Danish Association for Combating Venereal Disease and also for seven years president of the International Union against Venereal Disease. His interest in leprosy helped to make him a great traveller, and he did much to lighten the lot of the leper in many parts of the world, from Iceland to the West Indies. In 1897 he was the organiser of the first International Leprosy Conference, in Berlin, and from 1900 to 1914 he was the chief editor of an international publication on leprosy. His most important contribution to scabies was its ambulant treatment. A welcome visitor in many countries, it was particularly in France that he was known and appreciated. He died on May 6th at the age of 74.

THE PHYSICAL BASIS OF STUFFINESS

RECENT fluctuations from arctic to equatorial climatic conditions should stimulate interest in methods now available for the control of indoor temperature and humidity. The subject was discussed at the Royal Society of Medicine on May 28th (see p. 1401) when special consideration was given to the requirements of ships in the Royal Navy and in factories. In this country, where extreme conditions are rare, regulation of humidity is not usually employed in factories as it is in the United States, attention being concentrated on ventilation, temperature, and the extraction of dust. In a recent article¹ C. P. Yaglou of Boston considers the physical and physiological principles of air conditioning and collects a number of interesting observations. Although the percentage of CO₂ in the air may be used as a convenient guide to atmospheric purity this gas does not in itself produce discomfort in the concentrations ordinarily met with in stuffy rooms, imponderable amounts of organic matter appear to be far more effective in this respect, this observation has the support of experiments on the isolated frog's heart in which it was found that the weakening action of expired air was greater with old and sick persons than with the young and healthy. Dr Yaglou considers that the preference which still exists for window ventilation may be due to the monotony of the air movements produced by mechanical systems of ventilation which are found to be less stimulating than oscillating gusts of air coming through an open window. Dr Bedford's new book² on ventilation contains a chapter on air conditioning

in which a clear account may be found of the apparatus used for filtering, warming or cooling, humidifying or drying atmospheric air. Dr Bedford also notes the importance of organic matter in producing a disagreeably stuffy atmosphere, he quotes a table compiled by Dr Yaglou from which it appears that the number of cubic feet per minute required by a group of people is inversely proportional to the frequency with which they take baths. Thus school children of the poorer class require 38 cubic feet per min. each as compared with only 18 for children in a higher social grade.

AGAINST RHEUMATISM

REMARKING that most services are promoted by the force of public opinion, Capt G. S. Elliston, M.P., at the Margate Congress last month, said that first among the conditions now needing attention is chronic rheumatism. No steps, he said, commensurate with its importance have yet been taken, and he was right. Since he spoke, the welcome news has come of a gift of 10,000 guineas by Mr Alexander Maclean to the Empire Rheumatism Council to finance a rheumatism research unit, together with a promise of a further £2500 from the same source. The Council was constituted last November, when Lord Horder, as president, urged the need for a comprehensive research campaign for which the help of prominent citizens throughout the British Empire would be sought. In congratulating the Council on the success already achieved we take the opportunity of mentioning a modest appeal made some time ago for another and related enterprise. The International League against Rheumatism has done much to inspire the present interest in rheumatic diseases besides maintaining a quarterly journal, an information bureau, and a library; it has held five large congresses in European capitals, in which the medical profession and the governments concerned have shown great interest. The sixth congress is to be in England next year, and it is somewhat unpleasant to reflect that the English national rheumatism committees have hitherto not been in a position to give any financial support to the League's work, which has been supported, throughout the depression, chiefly by the smaller countries and, in emergency, by the honorary secretary. The League is likely to receive adequate support henceforward, but having missed the aid that might have been expected from this country it has barely struggled through the years of difficulty and must be restored to security. If any of our readers have rheumatic patients who happen to retain some faith in the value of international co-operation the appeal might fittingly be passed on to them. Of the £1000 asked for, about a fifth has been secured and the situation is one in which a small sum may do substantial good, since it will make possible the continuance of work that was formerly, and will again be, financed by regular national contributions. Cheques should be made payable, and sent to Barclays Bank Ltd., 54, Lombard Street, London, E.C.3.

EPIDEMIOLOGY OF THE BASQUE CAMP

THE arrival of 4000 refugee children from Bilbao confronts us with an old but ever fascinating problem. Should the 'herd at risk' be kept concentrated or scattered? In this particular case, should the Basque children be split up into units of not less than 50 or so and moved into the various homes prepared for them in different parts of the country, or should they, on health grounds, remain in their original camp at Lastkigh? If the children were experimental herds

¹ *J. Amer. med. Ass.* May 15th 1937, p. 1708.

² *Modern Methods and Principles of Ventilation and Heating*. By T. Bedford, D.Sc., Ph.D., Investigator to the Medical Research Council's Industrial Health Research Board. London: H. K. Lewis and Co. 1937. Pp. 85. 4s. 6d.

of mice it would seem better that they should be kept together provided no new additions were made to the herd rather than that they should have the chance of infecting other herds all over the country. But the children are not mice; and though their health record so far is good their camp was designed for a considerably smaller population and as the *House of Commons* was told last Monday it is highly desirable that the number of children there should be reduced as speedily as possible. The objection raised is that they would be going to homes and institutions some of which already contain healthy children and have no special medical arrangements in operation such as have been made at the camp. Again, in theory the argument seems to be chiefly in favour of delaying dispersal. But what are the actual dangers to be feared? The children were all medically examined before embarkation and those who took responsibility for the examination Dr Richard Ellis and Dr Audrey Russell give good reason for thinking that the risk of importing trachoma is by no means as serious as has been suggested. Two cases of diphtheria and three of measles have arisen among the 4000 children but have been suitably isolated. And finally there have been six cases of typhoid fever. All of these however have appeared within the incubation period since leaving Spain and presumably there is little likelihood of infection occurring after arrival in England. Hence we are not considering the dispersal of an unhealthy herd as in the poliomyelitis outbreaks of 1926 and 1932¹ but of a healthy one. The visitors to the Bournemouth Poole and Christchurch district who scattered back to their homes during the 1936 milk epidemic for example, presented a much greater risk to the country. At Eastleigh each child is to have three full medical examinations before leaving the camp.

The Ministry of Health though it has no direct responsibility has been asked for its advice and has been in direct touch with the camp authorities through its medical officers. Its advice is apparently after some hesitation to allow evacuation of children going direct to empty homes and institutions where they will not be in contact with other children—provided that the medical officer of health of the district is prepared to accept them. The remainder are being inoculated against typhoid and will be evacuated when immune. This advice we regard as sound. Medical officers of health are not likely to grudge any extra trouble the present policy may entail nor will they want to put unnecessary obstacles in the way of colleagues who have done and are doing a fine piece of humanitarian work.

The Inter Departmental Committee appointed in April 1936 to inquire into the restoration of working capacity in persons injured by accidents has made an interim report (H.M. Stat. Office 4d). The object to be aimed at is the covering of the country with a network of fracture services attached to existing hospitals whether voluntary or controlled by the local government authorities. A model scheme has been prepared by the committee capable of adaptation to the varying circumstances and needs of different localities and areas. The maximum size of a fracture clinic compatible with an efficient unified control is put at one capable of dealing with 3000 to 5,000 cases a year of which about one third would on a general average need inpatient treatment involving the provision of say 40 beds. The

needs of rural areas would be met by linking them up with a fracture clinic at some convenient centre to which cases could be transferred. The committee offers its assistance in any difficulties presented by the application of such a scheme to local circumstances. Sir Malcolm DeLoraine has presided over the committee whose medical members are Miss Muriel Bywaters, Mr W. A. Cochrane, Dr T. Ferguson, Prof E. W. Hey Groves, Dr J. F. E. Priceaux, Mr H. S. Souttar and Mr A. C. T. Woodward.

The inquiry into the physical psychological and genetic aspects of mental deficiency carried on in the research department of the Royal Eastern Counties Institution at Colchester has received valuable aid from the trustees of the Rockefeller Foundation. Hitherto the research department under Dr Lionel Penrose has been financed by the Medical Research Council the Darwin Trust and by the Institution itself. Recently also a generous donation of £2200 was made by the Hon. Alexandrina Peckover towards the cost of a new laboratory and research offices provided by the Institution. Now the trustees of the Rockefeller Foundation have opened the way to further developments by making a grant at the rate of £600 per annum for five years to provide additional research workers and a non-recurrent grant of £700 towards the cost of laboratory equipment.

Sir THOMAS NEILL who died last week at the age of 81 years, was one of the three insurance commissioners appointed by Mr Lloyd George when the Act of 1911 came into force. He had had much to do with framing the scheme itself from his long experience with the Pearl Assurance Company and after serving as commissioner he became chairman of the National Amalgamated Approved Society. This post he held until his retirement last year combining it with many other important executive offices. His judgment was sound and in conference his opinion was influential and decisive. He had a slight stutter but there was nothing hesitating about his mind which worked like a well-oiled machine. His decisions which were nearly always right were quickly made and tenaciously held though keen and firm in business he was one of the kindest hearted of men as his staff well knew. He found difficulty in passing street collectors on flag days and on Queen Alexandra's day he would arrive at his office richly decked with roses. He will long be regretted by those who worked with him.

AN account of the memorial to the late Sir Walter Morley Fletcher printed for the trustees of the memorial fund at the University Press Oxford has been issued to all the subscribers to the fund. It is embellished by two illustrations one of which shows Miss Dora Clarke's posthumous portrait bust of Walter Fletcher photographed from the clay model the other a corner of the library of the National Institute for Medical Research with the finished bronze in position.

LEWIS VICTORIA HOSPITAL.—This institution whose accommodation has lately been doubled needs an increased income of about £100 yearly if the work is to go on successfully. A nurses' hostel has been built and the hospital extensions proved more complicated and expensive than had been expected. Private wards had to be closed last year because of the work and the income of the hospital suffered in consequence.

SPECIAL ARTICLES

THE LISTER INSTITUTE

A YEAR'S INVESTIGATIONS

On June 2nd the governing body of the Lister Institute of Preventive Medicine, London, presented its annual report, signed by Prof William Bulloch, F R S, as chairman. The year has seen several changes in the staff working at the institute under the general direction of Sir John Ledingham, F R S. Dr E Weston Hurst left in September to become director of the Institute for Medical Research at Adelaide, Dr C Russell Amies (formerly a research fellow in bacteriology) and Dr A S McFarlane (research fellow in biophysics) have joined the staff, and on the departure of Mr J M Gulland, D Sc, in the autumn Mr A R Todd, Ph D, joined the biochemical department, of which Miss M G Macfarlane, Ph D, is now also a permanent member.

The following notes describe some of the many inquiries pursued during the year.

VIRUSES

Etiology of rheumatic diseases—Dr G H Eagles, with the assistance of Dr P R Evans, Dr J D Keith, Mr A G Timbrell Fisher, and Dr W H Bradley, has continued the study of a possible virus agent in acute rheumatism, rheumatoid arthritis, and chorea. Specific agglutination tests with the sera of patients suggest that these diseases have in all probability a common etiological factor, though other factors such as concomitant infection by streptococci probably play a part. Infection experiments have not so far given unquestioned confirmation of serological findings, but in two monkeys grave cardiac involvement has followed intrapericardial injection of rheumatic virus body suspension. In one instance the suspension was inoculated alone, in the second it was inoculated with a small dose of a streptococcal toxin. In both cases myocardial damage was revealed by histological study, but the typical Aschoff node was not demonstrated. Results of control experiments indicate that toxin alone is probably not responsible for the myocarditis. Experiments are under way to discover the cause of the prolongation, in monkeys, of the P-R interval, which is considered to a large extent pathognomonic of early rheumatic carditis in man.

Dr C R Amies has continued his investigations of the tumour producing agents in filtrates of avian sarcoma. His results confirm the fact that fowls bearing Rous sarcoma No 1 develop antibodies for the tumour agents. This immunity reaction can be demonstrated by neutralisation tests and also by agglutination and complement fixation reactions. It has now been found that the sera of rabbits which have been hyperimmunised with normal fowl protein exhibit strong neutralising activity against these purified suspensions of the Rous No 1 agent. The observations, so far as they go, are held to confirm experiments carried out some years ago by W L Gye and W J Purdy, on which their conception of the dual nature of the infective complex is largely based.

For some time Sir John Ledingham has been investigating the relationship of the viruses of rabbit myxomatosis (Surrell) and rabbit fibroma (Shope). It has been found that animals infected with the fibroma virus develop agglutinins for myxoma but often little or none for fibroma until a dose of

myxoma is given, when agglutinins for both appear in the serum. Dr E W Hurst passed the myxoma virus through the brains of rabbits and obtained a variant whose capacity to cause death after intra-cerebral inoculation was much reduced. The discovery of this variant should greatly facilitate further inquiries, for it is now possible to study animals that have recovered from myxoma without having to give them the fibroma virus first.

Staining of elementary bodies—Dr M Gutstein (Berlin) has elaborated a method for rapid staining of the larger virus bodies, based on the use of basic dyes in alkaline solution. No mordant is required and excellent microscopical pictures are obtained.

Vaccina—Dr M H Salaman has shown that the virus neutralising power of an antivaccinal serum can be removed by absorption with a sufficient dose of washed elementary bodies, but not by absorption even with large doses of the soluble antigen. On the other hand, precipitins and agglutinins could be absorbed from such serum in varying degrees by the bodies and by the soluble antigen.

ANTIGENIC CONSTITUTION AND IMMUNISING PROPERTIES OF BACTERIA

The Vi antigen of typhoid bacillus—Mr A Felix, D Sc, with Miss R M Pitt, has continued the investigation of the properties of the Vi antigen of *Salmonella typhi*. The conclusion that only strains containing both the O and Vi antigens possess the highest degree of virulence of which this organism is capable has been further strengthened. In spite of numerous attempts, a method of preparing anti-typhoid vaccine which would enable the Vi antigen to be preserved in its most effective form has not yet been devised. Dr Felix, in co-operation with Dr W D Nicol, tested the antibody response in 50 persons who had been given three doses of an alcohol killed typhoid vaccine by the subcutaneous route. A marked increase in the O antibody was observed in all those inoculated, and a significant increase in the Vi antibody in about half. But re-examination of the vaccine after storage for half a year, with or without the addition of phenol or tricresol, showed that the vaccines had almost entirely lost their capacity of stimulating formation of Vi antibody in the rabbit. Dr Felix has also been investigating the possible value of Vi agglutination in the detection of typhoid carriers. Sera from 45 carriers have been examined and the results suggest that Vi agglutination has a definite place in the routine diagnosis of typhoid carriers. It is noteworthy that all the 25 strains from chronic typhoid carriers examined were found to contain Vi antigen.

Dr H L Schütze and Dr P A Gorer are continuing their investigations of genetic constitution and immunity. Working with two pure lines and two selected lines of mice they have tested resistance to infection with *Salmonella typhi murium* and *S. enteritidis* also response to immunisation and the facility with which H and O antibodies are produced. Significant genetic and sex differences have been observed in resistance to infection and in ability to produce antibodies, but there seems to be no simple relationship between such ability to produce antibodies and natural resistance to infection.

Dr Gorer has studied the genetic basis of antigenic differences demonstrable in the erythrocytes of mice with special reference to the antigenic basis of tumour transplantation.

Two such antigens were found to depend upon single dominant genes. A sarcoma arising in a pure line of albino mice was found to be transferable to all other members of the line and certain hybrids derived from it but not to unrelated mice. It was found that all hybrids susceptible to grafts of the tumour possessed an antigen in their erythrocytes derived from the albino ancestors. If the antigen was absent the tumour invariably regressed. The sera of mice in which the tumour has recently regressed may often be shown to contain agglutinins for the erythrocytes of albinos. It was concluded that the fate of a transplanted tumour largely depends upon immunological differences between the transplant and tissues of the host.

MALE SEX HORMONES

Examination of the effects of the sex hormones has been continued by Dr V. Korenchevsky with the assistance of Mrs. M. Dennison and Miss K. Hall. The most remarkable property of the male sex hormones studied is their bisexual function—i.e. the property of stimulating the development of the sexual organs of both sexes in normal rats and bringing about a return of the atrophied organs of gonadectomized animals to or towards the normal condition. But whereas the restorative effect on all the sexual organs of the male rat is complete, in females the complete effect was obtained only when testosterone propionate was administered simultaneously with the female hormone (oestrone). It is also important to note that with oestrone alone it was found impossible to obtain (with the doses examined) a complete recovery of all the atrophied sexual organs.

The male hormones investigated may be arranged in descending order of activity as female sexual stimulants as follows: (1) testosterone propionate, (2) testosterone, (3) androstanediol, (4) androstenediol, (5) androstenedione, (6) transdihydroandrosterone, (7) androsterone. In ovariectomized rats, with a few exceptions, the male hormones produce changes—chiefly in the vagina but in some cases (testosterone propionate) in both vagina and uterus—similar to those seen during pregnancy. These are most pronounced when the male and female hormones are injected simultaneously.

Unlike the other male hormones, testosterone propionate has a stimulating though slowly decreasing action on the sexual organs for as long as 9 days after injection. For this period it completely maintains its effect on the adrenals, while the katabolic effect on the metabolism as shown by the changes in the body weight even increases. This property of testosterone propionate gives it an especial therapeutic value since results can be obtained with injections as infrequent as once in 10 or even perhaps 14 days.

RENAL FUNCTION—BLOOD COAGULATION

Prof. I. Ellinger and Dr. A. Lambrecht (Liège) have studied the localisation of the glycosuric action of phloridzin. They find that phloridzin interferes with the passage of certain substances from the lumen into the epithelium of the proximal tubules. The mechanism of this blockade has however not yet been ascertained.

The cerebro-spinal fluid in acromegaly.—Prof. I. Ellinger in collaboration with Dr. Dorothy Hare and Dr. S. Levy Shynsion has studied the influence of the cerebro-spinal fluid of an acromegalic woman on the urinary chloride and water excretion of rabbits injected subcutaneously with the fluid and given water per os simultaneously.

A slight increased rate of chloride elimination resulted but normal water diuresis was unaffected. On the other hand cerebro-spinal fluid from normal people and sera

from the acromegalic patient and other control patients had no action either on chloride excretion or on diuresis. This effect was less after irradiation of the pituitary gland, which also produced clinical improvement. In control experiments a standard solution of pitressin gave an antidiuretic effect as well as an increased rate of chloride excretion. It is concluded that the spinal fluid of the acromegalic patient contained sufficient amounts of a hormone of the posterior lobe of the pituitary gland but so far it has not been possible to decide whether the antidiuretic and chloride eliminating effects are due to different hormones or whether the antidiuretic effect of the posterior lobe hormone was masked by that of some other substance in the spinal fluid of this patient.

Dr. J. O. W. Barratt has completed his investigation of anticoagulant action. It has been found that sodium chloride, chlorazol and heparin resemble hirudin in producing their anticoagulant effect upon thrombin, no action upon fibrinogen could be observed. With improved technique it was possible to obtain an index of anticoagulative power and also to calculate coagulation times corresponding to varying concentrations of anticoagulant.

OBSERVATIONS WITH ULTRACENTRIFUGES

The two ultracentrifuges provided by a grant from the Rockefeller Foundation were completed in time for the visit of the designer, Prof. T. Svedberg of Uppsala in September (see *Lancet* 1936 2 874). The smaller equilibrium centrifuge which runs at speeds up to 18,000 r.p.m. has been found to be adaptable to the study of certain viruses and to the recently discovered virus proteins. Excellent sedimentation photographs have been obtained of tobacco mosaic virus protein and a study of the factors which determine its homogeneity in respect of molecular size is in progress. The behaviour of the blue respiratory protein (haemocyanin) of the blood of *Helix pomatia* has been exhaustively studied recently by Svedberg and may be used as a model of homogeneity in a substance of molecular weight of the order of millions. Preparations of elementary bodies from rabbit and sheep vaccinia virus have been investigated by means of the photographic technique and unexpected facts have come to light. Preparations of herpes virus have also been examined. A form of micropipette has been designed which enables fluid at different levels in the centrifuge cell to be accurately removed after the run.

The high speed ultracentrifuge running at the maximum speed for routine use (60,000 r.p.m.) has been used to study the sedimentation of human globin, serum albumin and serum globulin. It is also being used at lower speeds to investigate the behaviour of visual purple. On a visit by Prof. Svedberg in February the velocity centrifuge was run up to the maximum speed considered safe (65,000 r.p.m.) no trouble was experienced; this speed was maintained for four hours and opportunity was taken to analyse a specimen of horse serum.

NUTRITION

Vitamin A.—A collective investigation has been organized by Miss F. M. Hume as secretary of the Vitamin A Subcommittee in which ten different laboratories have participated to compare the results of biological and spectrographic estimations of vitamin A. The results showed a satisfactory degree of concordance and gave no support to any alteration of the value 1600 adopted for the conversion factor at the 1934 International League of Nations Vitamin Standardization Conference, but certain discrepancies leave a possibility that the spectrographic method

will have to be abandoned and vitamin A standardisation made to depend only on the biological test

Vitamin B₁.—Dr F Vivanco (Madrid) has investigated a specimen of "oryzannin" the crystalline vitamin B₁ hydrochloride prepared from rice polishings provided by Prof Suzuki. An average amount of 3.3 γ of the crystalline material had a potency equal to that of 1 international unit of vitamin B₁.

Ætiology of pellagra.—Miss Harriette Chick, D Sc, has collaborated with Mr T A Birch and Sir Charles Martin, F R S, at the Department of Animal Pathology, Cambridge, in experiments on the nutritive defects of maize

Young pigs were the experimental animals. The diet given contained over 80 per cent ground whole white maize supplemented with peameal and a small amount of purified casein to increase the protein content, extra salts and cod liver oil. Dogs maintained on this diet develop a disorder known as nutritional black tongue, characterised by anaemia, diarrhoea, and stomatitis with necrotic changes in gums and tongue which is held by many to be the analogue of human pellagra. After about six weeks on this diet the young pigs ceased to grow, showed a loss of weight, anaemia, and severe diarrhoea, and died unless the diet were changed. They showed no skin sensitisation to sunlight. The disease was prevented if 4 per cent yeast was included in the diet or if the maize was replaced by a mixture of wheat and barley, it was cured in a dramatic manner when yeast or an autoclaved protein free yeast extract was added to the diet. These facts pointed to a deficiency in maize of some heat stable constituent in the yeast extract—e.g., some constituent of vitamin B₁. Preliminary tests with flavin gave negative results and trials will now be made of other heat stable fractions and preparations from yeast extract. The above black tongue diet has been found relatively satisfactory for growth and maintenance of rats so that the missing anti black tongue (1 anti-pellagra) factor appears either to be non essential for the rat or to be adequate for this species in small amount. The pig, therefore, appears to be a more suitable experimental animal.

In continuation of his work in this field Prof Ellinger, together with Dr W Beckh and Prof T D Spies (Cincinnati) has studied porphyrin excretion in non endemic pellagra. In 10 out of 14 cases of "alcoholic" pellagra observed at Lakeside Hospital, Cleveland, U.S.A., an increased porphyrin excretion (coproporphyrin) was observed, the intensity of which showed a rough relation to the severity of the clinical symptoms. Dr Chick has been examining the nutritive value and light-sensitising properties of buckwheat in the hope of finding the causes of the light sensitivity characteristic of pellagra. A small daily ration (0.1 g) of the dried flowers caused a high degree of light sensitivity in albino rats, and Mr T F Macrae, Ph.D., is collaborating in attempts to isolate the active substance.

Wheat and bread.—Miss A M Copping has continued the investigation begun by M H Roscoe in 1935. As was to be expected more vitamin B₁ and B₂ was found in wholemeal flour and bread than in white flour and bread. The last two, however, proved to be unexpectedly rich in vitamin B₁ and control experiments with ground polished rice, in which the rats developed characteristic nervous symptoms of vitamin B₁ deficiency, emphasised the difference between polished rice and white flour in this respect. The content of flavin was low in both types of flour and breads, the white flour and bread being definitely inferior to the wholemeal. The second constituent of the vitamin B₂ complex (so called "vitamin B₂") was abundant in the wholemeal flour and bread and less so in the white flour and bread. The nutritive value of wheat flour and bread therefore appears to be limited by their low content of flavin.

(To be concluded)

MEDICINE AND THE LAW

Novel Point in Examination under the Lunacy Act

A FRESH pitfall for the medical practitioner seems to have been discovered in the Lunacy Act. The simple inference to be drawn from Section 285 is that a justice may direct a medical practitioner to examine an alleged lunatic and may order the examiner to be paid reasonable remuneration. A recent case in the county court at Ross on Wye, however, has disappointed the doctor who drew this conclusion. The disappointment was mitigated, rather than explained, by a passage at the conclusion of the judgment of the court. The plaintiff doctor, who was represented by counsel instructed by the Medical Defence Union, was said by the judge to have acted as any doctor of repute would be expected to act, especially upon the serious information he had received, the examination was made at the request of the justice of the peace and the proceedings were properly carried through. This judicial tribute was the more gratifying because there had, at committees of the defendant county council, been violent criticisms of the doctor's conduct and he was naturally aggrieved when these criticisms received publicity in newspaper reports. But, notwithstanding the judge's favourable comments, judgment was given against the plaintiff on his claim to be paid one guinea as reasonable remuneration under the section already cited.

In lunacy litigation where medical practitioners are concerned there is usually a complaint that certification has been too lightly made. In the case at Ross on Wye, the practitioner, after making his examination, declined to certify. The question of examination arose because certain information had reached the doctor. Whether the information was true or not the county court judge was not in a position to say, he was satisfied nevertheless that the doctor, having had that information, was bound to act as he did. In view of this expression of the court's opinion, it would perhaps be unnecessary to summarise the evidence, were it not that some statement of the facts is needed in order to show the apparent gap in the present law. The plaintiff doctor was medical attendant to a father, mother, and daughter. The daughter, whom we will call Miss X, was some thirty years of age. The doctor from his own observation had formed the opinion that she was unbalanced, but his view was evidently influenced by what he learnt from her parents who consulted him in great anxiety. She was said to believe it necessary to disinfect every body and everything. She was said to have poured disinfectants over her father and mother, to spend much of her time washing her clothes and her money in disinfectant, and to use a piece of paper or a cabbage leaf even for opening a door. One Sunday morning the doctor was summoned to the home of the family where he found the father suffering from a heart attack and lying on the floor as the result of an alleged assault by the daughter. The mother soon afterwards required medical attention for nervous breakdown attributed to the daughter's conduct. It was stated that on another occasion Miss X knocked her mother down and emptied a bowl of disinfectant over her. Miss X was also stated to have run about the garden without her clothes. The anxious parents asked the doctor's advice, they wanted to place their daughter in a nursing home. He suggested, as there was no home in the neighbourhood, that the daughter

should enter a mental hospital as a voluntary patient. The mother replied that the daughter would refuse to do so and that the fees were beyond her means. After further discussion the doctor was asked to speak to the local relieving officer. He did so and the officer brought him next day a form of certificate which included the usual space for facts communicated to him by others. He filled in this space at the request of the relieving officer who said it would save time. He seems also to have signed the certificate by mistake but the county court judge declared that the mistake was not one of any magnitude and could have no material effect upon the case. The relieving officer arranged for the presence of a justice of the peace and the parties (the justice, the relieving officer and the plaintiff doctor) went to the place where Miss X had her work. She was a school mistress and they went to her school—at her mother's suggestion since Miss X was apparently not sleeping at home. The justice said to the plaintiff: Will you go in and examine her? This was the direction on which the plaintiff relied under Section 285 and the justice in his evidence agreed that it had been given. Although they had fixed a time when school would be over there were two children still present. The doctor waited till they had gone and then discussed with Miss X the matters of complaint already mentioned. He ultimately came to the conclusion that he could not properly certify her: he went outside and said so to the magistrate. She asked who the people outside were and asked them to come in. The subsequent events, and in particular the complaints and criticisms of the doctor's conduct on the part of the defendant county council, were not placed before the court and were presumably irrelevant. The justice who saw Miss X stated in his evidence at the county court that there were no sufficient grounds for ordering her removal to a nursing home. Having satisfied himself of the terms of Section 285 the justice made an order for payment of reasonable remuneration "by the county council as the statute provides.

The county council denied all liability. It contended that Section 285 did not apply to the facts of this particular case. Its legal representative drew the court's attention to Sections 14, 16 and 17 of the Lunacy Act which relate to paupers deemed or alleged to be lunatic (or in the euphemistic language substituted by virtue of Section 20 of the Mental Treatment Act of 1930 rate-aided patients deemed or alleged to be of unsound mind). The council argued that Miss X, who was paid as a school teacher, could not be called a pauper. Section 13 relates to a person not a pauper and not wandering at large who is deemed to be a lunatic and is not under proper care and control. Section 16 relates to a person whether a pauper or not who is wandering at large. The council contended that none of these sections fitted the case of Miss X and that unless the action of the doctor could somehow be brought within the ambit of the Lunacy Act Section 285 (on which the plaintiff relied) did not apply. The court took this view; the plaintiff had to show that he had been doing some thing within the Act: he had failed to prove his case.

The claim was stated in court to have been the first of its kind. If it be indeed a *casus omissus* it would appear a proper matter for which Parliament should make provision when at length the law of lunacy is rewritten. The one consideration upon which everyone is agreed is that early examination and diagnosis is essential in mental treatment. This step can be taken only by bringing in the medical practitioner. In the facts under review it may be

that the practitioner the relieving officer and the justice acted under a misunderstanding of a series of complicated enactments. The medical practitioner was not negligent nor did he act in bad faith. There was obviously a proper case for investigation. If the justice could direct examination and could make the order for reasonable remuneration and if the county court judge could say that the plaintiff acted as any doctor of repute would be expected to act the county council might well have found itself able to honour the justice's order. Local authorities do not always behave prettily in litigation: there are ugly examples, for instances of their repudiation of liability for work ordered and completed where the contract was not under seal. But allowance must be made for a proper desire to protect ratopayers' pockets and for a natural susceptibility to influences local and personal.

Maclean's Stomach Powder

Members of the medical profession would scarcely encourage trade monopoly in the treatment of ill health. They do not seek to protect their prescriptions by patent for personal gain. It would be unfortunate for a doctor if after giving the public the benefit of his scientific research he were involuntarily to appear a party to its commercial exploitation. The case of Prof. Hugh MacLean, which comes to mind in this connexion has just been recalled in litigation before Mr Justice Farwell between two firms of manufacturers one of which was named Macleans Ltd. A report of the hearing (in the *Pharmaceutical Journal* of May 29th and June 5th) shows that the proceedings arose out of an application by Macleans Ltd. for an injunction to prevent a rival firm from passing off certain medicated sweetmeats as the goods of the plaintiffs. The defendant firm (Lighbown Ltd.) was marketing sweets advertised as containing Prof. MacLean's powder; it was also using the expression Maclean's sweets in a manner likely to deceive the public into thinking that the defendant firm was selling preparations made by Macleans Ltd.

If the main issue in the litigation was the confusion in the sale of sweets there was naturally an occasional allusion to the possible confusion due to the similarity of the name of Dr. Hugh MacLean and that of the plaintiff firm. The judge paid his tribute to the generosity of Dr. MacLean in giving the public the benefit of his work. Counsel and witnesses mentioned Dr. MacLean's research at St. Thomas's Hospital into the alkaline treatment of gastric ulcer and other ailments. His prescription was published; it was said in 1920 both in the *Pharmaceutical Journal* and in the *Chemist and Druggist*. In 1931 Macleans Ltd. the plaintiff firm introduced to the public a preparation named Maclean's Brand Stomach Powder. The firm had been founded by a Mr. Alex. C. Maclean; hitherto it had been concerned with tooth powders and other toilet requisites. It now sold the powder in bottles on which the name Alex. C. Maclean was printed. Mr. Lazell, a director and secretary of the firm told Mr. Justice Farwell of discussions with Dr. Hugh MacLean who had raised no objection to the firm's action. We were anxious, said Mr. Lazell in the witness box,

to do nothing which would harm the profession in the medical profession we coined the word stomach and in 1931 the powder was put upon the market; on the cartons were the words specially prepared according to the formulae of Dr. Hugh MacLean. Soon afterwards continued Mr. Lazell the firm received a letter from Mrs. MacLean taking

exception to this use of the name of her husband who was ill at the time. The words were consequently altered to "specially prepared according to the formulae of an eminent physician," and later were altered again to "prepared in accordance with the formulae used in the leading hospitals." Finally the words were altered to a mere statement that the formula was selected from a number of others. Macleans Ltd. had also registered the trade mark "Macs," and it sold throat lozenges under this name. The defendant firm, Lightbown Ltd., has been selling medicated sweets under the name "Merrimaes" which Macleans Ltd. said was calculated to deceive and cause confusion. In addition, as already mentioned the defendant firm had described its goods as "famous Maclean sweets," "Maclean sweets," and "containing the genuine Dr MacLean's stomach powder." Lightbown Ltd. set up a defence which unsuccessfully challenged the plaintiff's right to use the trade mark "Macs", with regard to the words "Maclean" and "Macleans," it was contended that they were not a trade mark, the defendant firm's sweets did contain stomach powder made up according to Dr Hugh MacLean's formula. During the hearing Mr Justice Farwell observed that he was more concerned with the sweets than with the powder, Dr Hugh MacLean had never made any sweets. The judge came to the conclusion that Lightbown Ltd. had made a deliberate attempt to filch from the plaintiff firm the reputation which Macleans Ltd. had made for its sweets. He granted an injunction to restrict the defendant firm's use of the name "Merrimaes" or the description "famous Maclean sweets" or "Maclean's sweets." He did not, however, grant one thing for which Macleans Ltd. had asked. He refused to issue any injunction in respect of the description "containing the genuine Dr MacLean's stomach powder." Macleans Ltd., he said, had no monopoly in the powder prescribed by Dr Hugh MacLean. The right to use Dr MacLean's prescriptions was not confined to any one person. Prior to 1931 "MacLean's powder," "MacLean's alkaline powder," or "MacLean's stomach powder" were terms "quite well known among doctors, to a large extent known among chemists, and to a lesser extent known among the public." Macleans Ltd. had made up this powder, put it on the market, and sold it under the signature of "Alex. C. Maclean", that fact did not prevent Prof. MacLean's powder being sold as MacLean's powder, Macleans Ltd. claimed no monopoly in the powder and could have none.

UNITED STATES OF AMERICA

(FROM OCCASIONAL CORRESPONDENTS)

BIRTHS, DISEASES, AND DEATHS

THE provisional mortality figures published in *Public Health Reports* for May 7th are based on data for twenty-five States and the District of Columbia for 1936. Mortality from all causes, which had been unusually low throughout the depression, increased in 1936 about 5 per cent over 1935, and the rate was the highest recorded since 1929. Only three States (Montana, South Dakota and Iowa) reported lower mortality than in 1935. Six diseases, however, registered new minimum death rates during 1936, these were typhoid fever, measles, whooping cough, diphtheria, poliomyelitis and diseases of the puerperal state. Scarlet fever was the only major disease of childhood which failed to register a new minimum

death-rate. Perhaps the most disquieting feature of the mortality conditions in 1936 was that the decline in tuberculosis mortality almost ceased in fact twelve of the twenty-six reporting districts noted increases. The so-called degenerative diseases—cancer, diabetes, cerebral haemorrhage and heart conditions—continued their upward trend. The combined mortality from influenza and pneumonia was the highest since 1929 and represented an increase of nearly 10 per cent over 1935. The birth rate continued to decline during 1936, it was 16.2 per thousand population, being 1.2 per cent below that for 1935 and 5.6 per cent below that for 1932. Ten States reported higher rates than in 1935, thirteen States lower rates, while three reported no change. Although the infant mortality rate increased about 2 per cent over the previous low record in 1935, it was still less than any other rate recorded. The report closes with the statement that "The time will soon come in this country, if present trends continue, when 95 per cent of the new-born infants will survive the first twelve months after birth."

AMERICAN PSYCHIATRIC ASSOCIATION

SOME 2000 neurologists and psychiatrists attended the 93rd annual meeting of this association held in May in Philadelphia. Among the 100 papers presented for discussion those describing the American experience of insulin shock in the treatment of dementia praecox were of major interest. The electrical activity of the brain cortex during epileptic seizures was described by Dr W. G. Lennox of the Harvard medical school, and the audience was fascinated by his suggestion that the solution of the problem of epilepsy must be sought in the chemistry of the gene. An increase is noted in puerperal insanity.

Data of great sociological import were disclosed in a case study by Dr Leo Kanner of Johns Hopkins University of 102 women released from the Baltimore training school for the feeble-minded. These girls were released on writs of habeas corpus granted by careless courts on the application of unscrupulous lawyers. The lawyers could not have obtained their fees without the interested collaboration of women in search of cheap domestic labour. None of the girls so released were paid normal servants' wages, some received no wages whatsoever. Of 102 girls released 17 acquired and transmitted serious communicable disease, 11 died before the age of thirty-two, 8 of them within five years of release. No less than 48 of the girls married. "Making every possible allowance," Dr Kanner was able to describe 10 of the husbands as "relatively stable and responsible individuals," 7 had prison records, 14 were habitual drunkards, 17 ultimately abandoned wife and family. To these hapless unions 165 children were born of whom 108 were "obviously and incontestably feeble-minded." Of the 102 girls 29 became prostitutes.

RABIES

THE daily press and the magazines have lately carried many scare stories about rabies. The situation has been well known to public health officials, and has been potentially dangerous for a considerable time in many different sections of the country. For several years rabies has been almost endemic among dogs and in districts where control has been relaxed human rabies has already appeared occasionally. In many districts stray dogs are allowed to become practically wild, and some of them have become rabid and bitten children without warning, and in many districts there is divided responsibility with regard to the handling of dogs and the reporting

of bites. The attention of the public is being called to these facts and already there has been some improvement in co-operation between various agencies. As has been pointed out in the medical journals the fact that the disease is primarily one of dogs has done much to enlist the support of humane societies.

THE ATLANTIC CITY MEETINGS

The annual meeting of the American Medical Association is to take place from June 7th to 11th, in Atlantic City, New Jersey. This occasion is usually accepted as an opportunity for the meeting of a number of other societies at or near the same time and in the same place. These include the American Bronchoscopic Society, the American Laryngological Rhinological and Otolological Society, the American Neurological Association, the Association for the Study of Allergy and the American Association for the Study and Control of Rheumatic Diseases. By this arrangement it is possible for a great many specialists to concentrate their major medical meetings into a relatively short period and to save a great deal of time and money in travelling—which, considering the distances involved, is of great importance.

THE 1937 CHRISTMAS SEAL

The National Tuberculosis Association has already published its design for the 1937 Christmas seals. This is no accident but part of a well planned publicity campaign which will make the American public more than ever seal conscious when the period between Thanksgiving Day and Christmas releases these most valuable revenue raisers for sale. The picture shows a bell-ringer lantern clasped in his left hand his bell swung vociferously above his right shoulder. The association is encouraging schools to study bell music and has arranged for the publication of a unit on bell music (a unit is a sort of brick in the structure of a school curriculum). They quote from Mrs. Coleman of Columbia University who will prepare this unit as follows—

The sound of stone or hollow resonant wood and of all the metals that come out of the earth have made a strange appeal to the mind and emotions of man. He has fashioned these materials into various forms—bells of some kind have been known all over the world—civilized and uncivilized—and practically all primitive peoples have used them. Rude tribes living in the remotest islands in the midst of the sea have been found to possess bells, and no matter how civilized and cultured people become they are still moved in some way by their sound."

When the art and science of salesmanship has progressed a little farther into the field of preventive medicine what wonders we may yet behold!

BUDAPEST

(FROM OUR OWN CORRESPONDENT)

THE CAMPAIGN AGAINST SYPHILIS

At a recent meeting of the Royal Medical Society Dr. Joseph Kiss, secretary to the Ministry of Health, detailed the development of the Hungarian campaign against syphilis. The decreased number of new patients at clinics and the diminished intensity of the disease among them of which there is statistical evidence provides but little information of the position in the country generally and the aim of the anti-syphilitic campaign is to reach patients infected with syphilis wherever they live. The spread of infection from patients with definite symptoms of

infection or those who present symptoms of other disorders in whom the disease is discovered by means of laboratory tests can be prevented but the problem remains of discovering and treating effectively those who harbour the infection and pass it on without knowing it. The most direct way of tracking hidden infections would be the systematic performance of serological tests but the present financial and economical conditions in Hungary do not allow the introduction of this costly solution which more over has disadvantages. A practical method for the discovery of a considerable proportion of infected persons suggested by Dr. Kiss was the serological examination of all pregnant women. On the assumption that 80 per cent of all macerated foetuses are syphilitic, an attempt since 1932 has been made to estimate the number of macerated foetuses amongst stillborn babies. The records from the obstetrical clinics and hospitals show that in 1933, 1934 and 1935 nearly 40 per cent of the stillborns were macerated making 12 per cent of the total births. After the birth of a macerated foetus at the Budapest obstetrical clinics the parents are advised to have a serological test made among deliveries taking place at the patients' homes no such advice has hitherto been given. During the period 1933-35 out of 6146 macerated foetuses 4673 that is 74.4 per cent, were born at home. It is probable that in the future these parents will be made to subject themselves to serological test and when reports are positive to undergo regular treatment. The National Sickness Insurance Institute already enacted that every single pregnant woman calling on the panel doctor must submit to such a test.

EFFECT OF PROSPERITY ON FERTILITY

In several European countries where the problem of legalised abortion has been discussed the opponents of strict prohibition always base their arguments on the importance of social position stating that in most cases it is poverty and the inability to bring up her child in comfort that drives the wife to the abortion monger. That this is a false assumption is proved by the everyday experience that it is not the poor that seek relief for getting rid of their burden but the well to do who are impelled by motives of personal comfort and vanity. In Hungary it is proverbial that in the Danubial beyond the Danube it is the custom to have only one child though this part of the country enjoys the greatest possible prosperity. The statistical returns relating to the fertility of married women, as shown by the census of 1930 point to the fact that the number of children of farmers and tenants holding over 100 acres of land averages 3.38 per family while in those with less than 100 acres the number is 3.75 and in agricultural servants and farm hands 4.20. These figures show the checking effect of property on the birth rate.

A COMMITTEE FOR THE PREVENTION OF BLINDNESS

After the formation of the International Committee for the prevention of blindness branches have been established in every country. The Hungarian committee was formed as a separate section of the National Public Health Association and its opening ceremonies were held recently. The president is the Countess Juliette Károlyi and the vice-president Prof. Emil Grosz. The latter speaking at the inaugural meeting detailed the history of international organizations against blindness. He said that in Hungary there are about 6000 persons incurably blind and of these the vision of about 2,000 could

have been saved if precautionary measures had been applied in time. The most important tasks are to diminish the devastation of infectious eye diseases and to check the occurrence of industrial accidents in connexion with the eyes. The committee has set itself as one of its tasks the education of those with impaired vision.

STILLER'S CENTENARY

Hungarian physicians have just celebrated the centenary of the birth of the late Prof Berthold Stiller, physician and director of the Jewish hospital in Budapest. His treatises on the asthenic constitution—his morbus asthenicus—began to appear in the 'nineties, and these were collected into one volume in 1907. He enumerated certain diseases, particularly pulmonary tuberculosis, to which the asthenic type is specially predisposed, and he pointed out that there are other diseases that do not occur at all in this type of subject. In his description he paid most attention to certain anatomical peculiarities, especially to a mobile tenth rib, as well as to a laxity of the connective tissue, giving rise to the visceral ptoses. He was also the founder of the science that investigates the connexions between bodily constitution and character, and which is generally attributed to Kretschmer. Accordingly Calvin, Schuller, Rousseau, Frederick the Great, and Robespierre were asthenics and their individualities were determined by their stature. A leading article in THE LANCET reviewed the book at the time and paid tribute to Stiller's "admirable critical faculties." Though the seed sown by Stiller proved very fertile, it did not meet with such a general recognition in Germany as elsewhere, but some years later they too acknowledged his merits and the importance of his work. But Stiller was not only an observant natural philosopher, he was also wholly a physician. Toward the end of his life he entered into a fierce dispute with the prominent Danish surgeon Rovsing, who advocated treating gastroptosis and nephroptosis by operation, while Stiller himself believed in improving the general condition and tuning up the whole body.

PARIS

(FROM OUR OWN CORRESPONDENT)

TUBERCULOSIS CAMPAIGN IN AN INDUSTRY

THE Michelin works at Clermont-Ferrand not far from Paris, present a useful object-lesson in community welfare with special reference to tuberculosis. At the beginning of this century, this industry, with some 22,000 souls dependent on it in the town began to set its house in order, pulling down slums and replacing them by model houses at a moderate rental. Between 1909 and 1930 3087 such model dwellings were built and by 1932 the slum area had ceased to exist. In 1915 Michelin made those family allowances which in 1932 became compulsory by law for the whole of France. In 1921 a dispensary was organised for the benefit of the tuberculous and the pre-tuberculous, and while in 1922 as high a proportion as 13 per cent of the attendants at this dispensary represented advanced cases in 1935 the proportion was only 1.5 per cent. The Grancher system of boarding out children exposed to infection in their homes has also been adopted by this community, and of the 229 children found to be exposed to infection between 1922 and 1927, 147 were promptly isolated, 23 were isolated after some delay and 59

were left in contact with infectious cases, and the tuberculosis mortality in these three groups was 0.6, 13, and 25.4 per cent respectively. Finding that applications for sanatorium treatment meant intolerable delays, the directors of Michelin opened a sanatorium of their own in 1926 with 90 beds. Here there is no limit to the duration of treatment, and 70 per cent of the patients admitted to this institution have been discharged under the heading "amelioration présumée durable." Children exposed to infection are given BCG and are examined at the dispensary three or four times a year. Thanks to these and many other benefits, the incidence of tuberculosis among the 22,000 members of the Michelin community has been greatly reduced. In 1931 there were 181 new cases of tuberculosis discovered in the community. The corresponding number in 1936 was only 84—a fall from 8.2 to 3.8 per 1000 inhabitants.

AMATEUR THORACIC SURGERY UNDER A CLOUD

In a circular letter dated April 7th, addressed to French prefects by the Minister of Public Health, attention is drawn to the fact that during the last few years surgical methods of treatment of pulmonary tuberculosis have not ceased to improve and now have become common practice in sanatoriums. But such operations should be in the hands only of skilled surgeons with adequate clinical and operative experience. The Minister of Public Health, on the advice of the Tuberculosis Commission, has therefore ruled that the names of all the doctors undertaking the division of pleural adhesions, phrenectomies, thoracoplasties, &c, in public sanatoriums must be submitted to him for his approbation with a complete dossier concerning their ages, addresses, and qualifications with special reference to their fitness for such work.

GUIDANCE FOR FOREIGN MEDICAL STUDENTS AND DOCTORS IN FRANCE

Although I have already referred from time to time to the Association pour le Développement des Relations Médicales entre la France et les Pays Étrangers, it may not be amiss to refer to it again now that during this summer and autumn Paris will be more than ever a centre of medical studies, not least post-graduate studies. The offices of this association are in the Salle Béchard, Faculté de Médecine, 12, rue de l'École de Médecine, and they are open every day from 9.30 to 11 and from 2 to 5 except on Saturdays. At these hours Mademoiselle Huré, who is Prof Hartmann's right hand, gives advice to students and doctors as to where they should go and what they should see. Her telephone numbers are Danton 09 59 or Danton 55 36.

In the quarterly bulletin of the association dated April, 1937, Prof Hartmann, who is the president, gives some instructive figures with regard to the attendance of foreign medical students and doctors at the Paris medical school since 1929. He deplores the change which has come over the scene in the interval owing to the world crisis, currency difficulties, xenophobia, and the competition of brand new buildings and schools of medicine in the South American countries. While in 1929 there were 293 foreign medical students registering in the Paris faculty of medicine the corresponding figure in 1936 was only 31. It might have been thought that Mademoiselle Huré's work would have diminished in proportion to the decline in the number of foreign medical students but of late French medical students have found their way in increasing numbers to her office, and her services have been much in demand.

in connexion with post graduate classes in Paris. On this subject Prof Hartmann is hopeful. As he points out there has of late been an encouraging rise in the number of such courses—a rise which assuredly reflects the growing appreciation they enjoy. In 1933 the low water mark for several years there were only 1013 persons attending these post graduate classes whereas in 1936 the corresponding number was 1200. It is certain Prof. Hartmann writes, that if these courses were announced early enough if they were well co-ordinated and well organised we would see a considerable rise in the number of their attendants. Might it not be possible for arrangements to be made between the French University authorities and the Anglo-Saxon press to give effect to this suggestion?

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

THE FACIAL EXPRESSION OF THE SICK CHILD

At a meeting of the Medico-Chirurgical Society of Edinburgh last week Dr William Brown, senior physician to the Royal Hospital for Sick Children, Aberdeen, spoke of the face and facial expression in the sick child and showed illustrative lantern slides. He pointed out that the maldevelopment of the lower jaw is often due to faulty methods of feeding and that the adenoid faces may be caused by various disturbances of the upper respiratory tract. An excess of hair is common in cases of mental deficiency but is often seen in children suffering from diseases of the lung; long eyelashes are often observed in tuberculosis. The colour of the child's face should be studied during sleep owing to the frequent vasomotor changes which occur when the child is awake. Cyanosis in infants generally means heart disease. A unilateral malar flush may indicate the side of the lesion in lobar pneumonia. Herpes is seen in pneumonia and other respiratory infections but also in meningitis. Thick and everted lips occur in severe mouth infections and also in cases of severe cough, when it is accompanied by cyanosis and swelling of the eyelids. Thrust is indicated by an open mouth and a dry tongue and when these signs are present fluids should be introduced by every available route. An open mouth or its opening and shutting also suggests hunger and the sight of a bottle produces the sucking reflex in such cases. Wasting may be due to loss of fat or loss of fluid, the last fat to disappear from a baby's body is the sucking pad in each cheek. Dehydration has a distinct facies which calls for the urgent administration of fluids, the orbits are hollow, the fontanelle is depressed, the eyes sunken and staring and the skin of the lower jaw loose and redundant. In cases of pyloric stenosis the forehead is lined with parallel horizontal furrows, an appearance according to Dr Brown almost diagnostic of this condition. The sudden development of oedema suggests frontal sinusitis or cavernous sinus thrombosis. Oedema of the eyelids is often observed in children who have been starved; persistent oedema involving only one eye may occur in middle ear disease. It is important to observe the eyes of infants, a sign of pain is wide dilatation followed by contraction. In a congenital heart disease the eyes are often dark brown and very bright. The sudden onset of squint or ptosis suggests meningitis but temporary ptosis may occur in middle ear disease. The appearance of open fixed eyes when the child takes

no interest in his surroundings is a bad sign. When the child is conscious, has wide open eyes and finds difficulty in breathing pyelitis is often present. The facial expressions of children are simple and in infants there are only three—complete repose, pleasure or annoyance. Dr Brown referred to the mask-like face of chorea and pointed out that the reappearance of expression is a sign that the acute stage is passing off. The child suffering from Pink disease is really miserable. He cannot sleep, eating is painful and the extremities are tender. Infants and very young children never smile when seriously ill so that the first smile is a welcome sign of improvement.

OCCUPATIONAL THERAPY

The annual report of the medical superintendent of the Astley Ainslie Institution, Edinburgh, shows that the number of patients who entered the institution was 1077 during the past year and that the average stay for each patient was 9.5 weeks. Fifty-one of the patients had been in the institution for over six months. The maintenance cost per bed for a year is now £151. An interesting development has been the building of an occupation therapy department which was opened in May of last year. The building has one storey and consists of a central section with two large wings projecting from either end to conform with the butterfly pattern of the existing pavilions. The wings contain the main work shops, one for the quiet crafts such as weaving, painting, basket-making and the other subdivided into two arms, the larger for the noisier crafts such as carpentry, the smaller for pottery work. Large windows form the greater part of the wall space of the main workshops so that when the weather is suitable the patients work under open air conditions. The daily average number of patients treated in the workshop has been 97.

IRELAND

(FROM OUR OWN CORRESPONDENT)

FEES FOR INOCULATION AGAINST DIPHTHERIA

The annual meeting of the Irish Free State Medical Union was held in Dublin on June 3rd when Dr Conor Maguire was re-elected president for a second year. The report of the council stated that there were 871 members on the register of the Union at the end of 1936. The number has increased considerably since that date. It was announced that arrangements were being made for the publication of a monthly journal and that the first number would be issued on July 1st.

A long discussion took place on the question of the remuneration for the work of immunisation against diphtheria. The demand of the Union hitherto has been for a fee of two guineas for a season each season to cover not more than twelve completed cases. The Minister for Local Government and Public Health had refused to sanction fees greater than 1s 6d per case where the one injection method was followed and 2s 6d per case where the three injection method was followed. For several months past country practitioners have been engaged in the work receiving no fees but leaving the settlement as regards fees in suspense. Dr J. P. Shanley, honorary secretary of the Union, related the steps that had been taken to secure a satisfactory settlement. Recently the parliamentary secretary had suggested

a sessional basis for remuneration, a fee of one guinea to be paid for each session of twelve patients. As this was worse than what the department had previously been willing to sanction, the offer had been refused. The medical secretary, as the result of inquiries made in Belfast and London, had found that in Northern Ireland the two injection method was most in use, and a fee of 2s 6d was given for each injection. In England the fee varied from 5s to 10s per injection, the medical practitioner supplying the material in the areas where the higher fees were paid. After protracted discussion a resolution to the effect that the fees should not be less than 2s 6d per injection was passed, and if this offer were not accepted within four weeks it would be withdrawn.

ANNUAL DINNER OF THE UNION

The first annual dinner of the Irish Free State Medical Union was held on the evening of the annual meeting in the Dolphin Hotel, with the president in the chair. Over a hundred members and guests were present, including Mr Sean T. O'Kelly (Minister for Local Government and Public Health, vice-president of the Executive Council), Mr Alfred Byrne (lord mayor of Dublin), Dr Denis Coffey (president of University College), and Mr P. Doran (chairman of the Hospitals Commission).

THE DUBLIN HOSPITAL PROBLEM

The daily press of Dublin has given wide publicity recently to a plea made in the annual report of the board of governors of Sir Patrick Dun's Hospital that the Minister for Local Government and Public

Health should come to a decision about the future of the Dublin hospitals. Attention is drawn by the governors to the recommendation made to the Minister by the Hospitals Commission some eighteen months ago in favour of the development of four large voluntary hospitals in Dublin, each to contain accommodation for some five to six hundred beds. The governors believe that the Commission under estimated the needs of Dublin. They point out that the demands for hospital accommodation are steadily increasing. In order, as far as possible, to meet these growing demands, the governors have, as a temporary expedient, found it necessary to use stretchers and temporary beds, yet many patients have had to be turned away for sheer lack of space. This condition clearly cannot be allowed to continue. Even if the Minister decides on the erection of five large hospitals, much time must elapse before the buildings can be occupied. During that time temporary accommodation must be provided. Sir Patrick Dun's is one of four small hospitals which accepted cordially the suggestion of the Hospitals Commission that they should amalgamate to form one hospital of 500 or 600 beds. They believed that the era of small hospitals had passed, and that larger hospitals must be built if efficient service was to be rendered. Their proposals have been before the Minister for some eighteen months, backed by the support of the Hospitals Commission, but they have been unable to obtain a decision. They must make some provision to meet the demands on their service and accommodation. They are waiting to be told whether the provision is to be temporary or permanent.

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations. Each contributor is responsible for the section for a month, his name can be seen later in the half yearly index.

BY TWELFTH MAN

II

It has been said repeatedly in recent years that surgery is the greatest of the arts. When I first read this I believed the writer to be jesting, but as the assertion was frequently repeated I concluded that it was intended to be a statement of fact. The psychologist would regard this as a "wish fulfilment" definition. For if surgery is the greatest of the arts and X the greatest living surgeon, then it follows that X is a finer artist than Brangwyn or Sickert, Epstein or Gill, Tom Webster or David Low. In fact, as Arnold Bennett used to say, a terrific swell.

An artist creates beauty but a surgeon creates nothing. Moreover the surgeon works in perishable material and the artist who uses his hands is careful to select a medium that has durability.

"But beauty vanishes, beauty passes,
However rare, rare it be,
And when I crumble—who will remember
This lady of the West Country?"

Or indeed the surgeon who defiled her beauty with his so lovely gastrojejunostomy? Surgery must be placed amongst the crafts, but here again it takes a lowly place unless the crafts are being adjudged solely for their dramatic quality or utilitarian value, when it goes top. Surgery may confer imperishable value on the human race by prolonging the life of a true artist or a real craftsman. But it may render

dictators the same service. Who can hope to cast the balance sheet of such indiscriminate life-saving?

* * *

This desire to make the best of a world other than one's own has something to do with the complaint that clinicians are so infrequently awarded the Fellowship of the Royal Society. Lewis, Trotter, Parsons, Gordon Holmes, and a few others and the list is complete. I think there is little reason to complain. The first-class clinician, be he physician or surgeon, rarely adds much to the sum of human knowledge, his chief claim to distinction is his highly developed clinical skill which dies with him. Moreover, he gets a larger share of material success than falls to the lot of the pure scientist—honours, wealth, and fame. Not that an F.R.S. is always a badge of poverty and social insignificance.

* * *

Hospital staffs were just emerging, when I was a student, from the sometimes mild but often bitter antagonism which existed between physician and surgeon. Physician and surgeon are now united, as brothers engaged in empirical living, before the cold disdain of the scientist and research worker. No doubt we shall soon have passed through this phase also, but the clinician is sometimes stimulated to counter reaction. A London Surgeon wrote in *Grains and Scruples* that "most men who undertake research

of set purpose do so less from a passion for discovery than from a knowledge of their own inadequacy for the battle of life from a desire for some sad mechanic exercise like dull narcotics numbing pain." A Doctor without Patients replied that "our faculty suffers too much from mutual scorn. Sir A. B. in Harley street sneers at the lough browed Prof. C. A. cleverish man my dear fellow but no breadth at all, no vision and secretly fears and envies C's exact knowledge. Prof. C. entertains his friends with anecdotes of that priceless fool B's ignorance and is secretly annoyed that B can afford a better car and more exciting holidays than he. They really know very little one of another."

The opinion of A. London Surgeon is elaborated by Aldous Huxley in his recent novel *Eyes in Giza*—"Scholarly philosophers, men of science—what other class of men has succeeded in getting the world to accept it and more astonishing go on accepting it at its own valuation. But in fact the Higher Life is merely the better death substitute. A more complete escape from the responsibilities of living than alcohol or morphia or addiction to sex property. The Higher Life can fairly wallow in his good conscience. For how easy to find in the life of scholarship and research all the equivalents for the usual virtues—Obedience of artistic and mathematical form, Imitation of scientific research, Courageousness of thought, Bold hypotheses, Logical integrity, Temperance of views, Intellectual Humility before the facts. All the cardinal virtues in fancy dress. The Higher Lifers come to think of themselves as saints—saints of art and science and scholarship. This I take to be Aldous Huxley's way of saying that he is every bit as good a man as was his grandfather the great T. H. But seriously which of us avoids this sad mechanic exercise? I can't live for all of us as A. Doctor without Patients said, one damned thing after another in the eighteenth or the twentieth centuries, country practitioners or university professors? I see no battle of life in the laboratory (I have thee by the throat, thou million murdering death!) Are we not all, in some sense, escapees from responsible living? Who shall cast the first stone?"

The desire of some clinicians to see their art transformed to an exact science is understandable but it is less excusable in our day when science itself is regarded as a form of art, an imaginative picture constructed by the human mind of the workings of the universe—and when as C. E. M. Joad has said the kind of information which science has to offer in respect of many things is not generally regarded as the kind of information which matters. I once heard Sir Almroth Wright address an audience of medical students and in inimitable fashion abjure them to see like the devil from the *salus empericus* and clung as they would to their hope of salvation to the *passus scientificus tutus*.

Listen to two doughty and distinguished opponents of this conception of clinical medicine as a science. A Rusticating Pathologist wrote "I was rather shocked to read in THE LANCET the other day that the conservator of the Hunterian Museum thought that the student should be well trained to the experimental method because he would find when he came to clinical work that diagnosis was conducted in the same way." This is either bad experiment or bad medicine. It has always seemed to me that the great trouble of the doctor is that he has to do sums

with numbers which are often very uncertain and his great pride that he usually gets the answer some where near right. If he failed to come to a conclusion adequate for action he would be a bad doctor. If he drew a conclusion from such froward data he would be a worthless experimenter. And, again as a patient I judge that his first business is to be a doctor. To cure a patient without knowing what is wrong with him is no mean performance. And Sir Auckland Geddes most unexpected of allies: "The real business of clinical medicine was not science. It was a personal relationship into which much sincerity and medical knowledge were suffused by the physician and trust and some dependence on the patient. Too many come to the sick room thinking of themselves as men of science fighting disease and not as healers with a little knowledge helping nature to get a sick man well. Beyond their scientific knowledge of man lay an incompletely explained area in which important things happened without discernible physical cause. Once they had ceased to fear what seemed to them non rational and recognised that human reason could not grasp all reality they could get to know a good deal about man." This view of the function of clinical medicine does not on the one hand require the abrogation of human reason nor on the other neglect the new knowledge which streams from laboratories.

Before I leave this matter of clinical medicine let me refer to this new "this happy breed of men" the Clinical Scientists. It will be interesting to see just how much clinical medicine benefits from the attempt to apply laboratory methods in the investigation of disease in the human subject. It is one thing for men of genius like Thomas Lewis and James Mackenzie after many years of varied activity deliberately to limit themselves to work in a restricted field. They will certainly produce results of value. But the neophytes who follow them patiently imitative having known no other good than this and desiring none will they too bring in the sheaves with them? How can the self-sterilised be fecund? I met a precocious young man just down from Oxford who when I asked him what he was going to do told me he was going to be a dramatist. He ignored the fact that dramatists begin life as actors, journalists, authors, shop assistants, stockbrokers, barristers, dramatic critics, schoolmasters, and doctors for the sufficient reason that life is the dramatist's workshop. So it is with clinical research. A man will only pursue his own ideas with passion and profit. Fruitful ideas for clinical research will arise in the course of clinical practice so that the clinical scientist must evolve from the practising clinician. It is therefore no coincidence that James Mackenzie and Thomas Lewis each began a scientific research into clinical problems late in life. To encourage young men to become clinical scientists by giving them whole time salaries which do away with the need for clinical practice is as absurd as it would be to attempt to create a new School of British Drama by putting all the potential dramatists in a closed community compelling them to do nothing but read Shakespeare, Sophocles and Shaw.

This week I have stolen too much of other men's thunder. With shame I recall that A. Public Health Clinician wrote "To day with the passage of the years I rarely use quotations but I endeavour to express myself clearly and give no one else credit for my ideas. How he must deprecate my derivative performance."

¹ Guide to Modern Thought. London: Faber and Faber.

PANEL AND CONTRACT PRACTICE

Court Finding on Capitation Fee

THE Ministry of Health issued on June 7th the finding of the court of inquiry set up by the Minister of Health and the Secretary of State for Scotland under the chairmanship of Lord Amulree, to consider the question of the capitation fee payable to medical practitioners under the scheme of National Health Insurance. The court was asked to investigate the question whether any, and if so what, alteration ought to be made in the amount of the doctors' capitation fee, having regard to any changes since 1924 in the cost of living, the working expenses of practice, the number and nature of the services rendered to insurance patients, and other relevant factors, and on the assumption that as from Jan 1st, 1938, employed persons under the age of 16 will have become entitled to medical benefit by virtue of amending legislation. The finding of the court is that the appropriate capitation fee should be 9s, the figure at present obtaining in regard to insured persons over the age of 16.

The introduction of legislation to entitle boys and girls to medical benefit immediately on becoming employed after reaching the school leaving age has awaited this decision, and the Ministry hopes it will now be possible to introduce the necessary bill in Parliament.

Delayed Acceptance Forms

The London medical benefit subcommittee asked the service subcommittee to investigate a case in which a practitioner had been remiss. In July, 1936, his attention had been drawn to the fact that during 1935 he had submitted only five acceptances and then on March 31st, 1936, he had submitted no less than 165. A temporary improvement followed but from Sept 30th, 1936, to April 1st, 1937, no acceptances were submitted. On the latter date 101 medical cards were submitted, some of which had evidently been in the possession of the practitioner since October, November, and December, 1936. The doctor told the subcommittee that he understood other practitioners were in the habit of submitting acceptances once a quarter and he had not appreciated that by retaining the medical cards he had in fact committed a breach of the terms of service. The subcommittee pointed out to him that the seven days' limit, laid down in Clause 3 of the Allocation Scheme, was not a troublesome piece of red tape but was an essential part of the machinery for the provision of medical benefit. Apart altogether from the interference with efficient administration the insured persons had been deprived of their medical cards which was likely to cause inconvenience if they should require treatment away from home. The report of the subcommittee points out that this is the first time they have been called upon to deal with a breach of the terms of service of this nature but they understand that the practitioner concerned is by no means the only offender. Beyond deciding that there had been a breach of the terms of service the committee took no action but they indicated that should there be a repetition of the offence they would feel compelled to take a more serious view of the matter. The practitioner has in effect fined himself because in many cases he neglected to submit acceptances during the quarter in which they were made.

Interference with Choice of Doctor

Two doctors were in partnership and, as sometimes happens, were not on speaking terms. The partnership was to be dissolved, and the junior who was going out found that insured persons whom he had accepted were receiving medical cards bearing the name of the senior partner. The insurance committee had an examination of the acceptances made when it was clear that in a number of cases the junior's signature had been erased or obliterated and that of the senior substituted. Certain insured persons were interviewed by the medical service subcommittee and made it clear that they wanted the junior partner, and in some cases did not even know his colleague. The senior partner admitted the deliberate alteration of the medical cards because he thought that as the junior was leaving the practice shortly it was absurd for him to continue to accept patients. He accordingly instructed the secretary to the partnership to intercept acceptances by the junior and to submit them to him for signature. He had no ulterior motive and at the time quite failed to appreciate that he was treating the wishes of the patients as of no effect. He offered to consent to the transfer of any of the patients to other doctors but the subcommittee decided against this, instead they caused the acceptances to be cancelled and open medical cards to be sent to the insured persons. The secretary admitted having held up the acceptances (although she had been told to send them in weekly) and having erased the junior's signature, saying that she regarded herself as employed by the senior and that she did not feel it her duty to tell the junior what she had done. The subcommittee had no doubt that the strained relations between the partners explained in some degree the action taken by the senior. There was no attempt at forgery—the alterations were obvious—nor was there any financial advantage to the senior because the profits had to be divided in accordance with the partnership deed. On the other hand they regarded as serious the interference with the right of insured persons to choose their doctors. There being no provision in the terms of service which the senior partner could be held to have infringed the committee simply put on record that the actions of the senior partner were deserving of censure.

Approved Societies and Hospital Treatment

The Central Bureau of Hospital Information has just published a useful addition to the numerous memoranda prepared for the assistance of hospital administrators. Memo No 108, replacing Memo No 49, contains (1) a list of the approved societies which have included hospital benefit in their fourth valuation schemes of additional benefits, and (2) a list of approved societies which, although not providing hospital benefit, yet allocate an annual sum for the purpose of making donations to charitable institutions, including hospitals. There are 273 societies in the former list and 85 in the latter, and among the 273 societies providing hospital benefit are 70 which in addition, make donations to hospitals and other charitable institutions. It is not so widely known as it should be that approved societies are not only empowered to set aside an annual sum from which to make donations to charitable institutions, but may also, with the consent of the Minister of Health include hospital benefit in their scheme of additional benefits adopted

after the completion of the fourth valuation. Payments made to hospitals by a society providing the benefit are based on the number of the society's members treated as inpatients and the duration of the period of treatment in each case and it is necessary for a hospital in applying to the societies for payment in respect of their members treated to furnish to the society a quarterly statement containing certain particulars of each patient which are set out in the memorandum. Payments are made only in respect of those members who were in the society during the period in which the surplus accrued out of which hospital benefit is payable. Copies of the memorandum which seems indispensable to all hospital administrators can be obtained from the Director of the Bureau 12 Grosvenor crescent London S W 1. The price for single copies is 4d post free and for 12 copies 3s 6d.

THE LANCET 100 YEARS AGO

June 10th, 1837 p 410

FROM A CALEDONIAN SURGICAL REPORT

"EXTRAORDINARY SURGICAL OPERATION.—In passing along the South Bridge yesterday forenoon, our attention was attracted by a great crowd of gentlemen at the gate of the Royal Infirmary pressing inward. Joining in the crowd, we were carried along with it to the surgical hospital, where we found the operating theatre crammed to excess chiefly by medical gentlemen and students amongst these we recognised Sir George Ballingall Dr MacLagen, Mr Newbigging Dr Campbell, the surgeons of the 14th Light Dragoons and 42nd Regiment besides many country surgeons. The excitement we have described was occasioned by the knowledge that an operation never performed in Great Britain was to be done upon a young man by Professor LIZARS. The case was what is technically called aneurism of the subclavian artery so near the heart that the flat large trunk required to be tied namely the *arteria innominata*. The young man, a carter from Dalkeith was placed upon the table and the Professor commenced by making an incision in the neck and progressively cut down to the artery when the ligature was applied. The operation was completely successful. The patient who bore it with uncommon fortitude was only on the table for fifteen minutes altogether. Thus as we have already said is the first operation of the kind which has been attempted in Great Britain. We understand that it was once successfully performed at Berlin by Dr Graefe and once in New York by Dr Mott.—*Caledonian Mercury* June 1.

"* The details of this case were set out with a full description of the technique of this operation at which the patient was not 15 minutes on the table in the issues of THE LANCET on the same volume dated June 17th p 445 and July 15th p 602. The patient survived for 21 days after the operation.—P D L

From lectures on *Materna Medica and Therapeutica* delivered by GEORGE G. SIMMOND M D at the Windmill street School of Medicine p 396

It is in the paroxysm of spasmodic asthma that stramonium has been most generally used—formerly very often without first seeking that a life and assistance which should only be sought from the medical man of long experience and careful observation. Indeed the paroxysm of embarrassment of breathing is so very distressing that an individual flies to every object which holds forth to him a promise of relief; and hence it is that the bold and imprudent adventurer has so often chosen as the province in which he will carry on his nefarious practice diseases of the respiratory organs. A sufferer will have recourse to any remedy that he believes can control the disease and for instantaneous relief he will encounter any difficulty. During the paroxysm life is insupportable

MOTHERS AND CHILDREN

(FROM A CORRESPONDENT)

THE seventh English speaking Conference on Maternity and Child Welfare was held in the great hall of B.M.A. House on the first three days of June. The decision to hold it a month earlier than usual enabled many distinguished visitors who had come over for the Coronation to take part.

HISTORY OF THE CHILD WELFARE MOVEMENT

Reprints¹ of a brief history of the child welfare movement written by Dr G F McCleary chairman of the Association of Maternity and Child Welfare Centres, were distributed beforehand to the delegates to enable those unfamiliar with the history of the movement to grasp how it came about. The urge to do something sprang from the *Congrès international des gouttes de lait* in Paris in 1905 at which were present, besides himself Bailie W F Anderson and Dr A K. Chalmers of Glasgow Dr S G Moore and the late Alderman Benjamin Broadbent of Huddersfield. Largely owing to the influence of these British delegates the movement quickly took root in Britain and in June 1906 the first Conference on Infantile Mortality was held in London under the presidency of Mr John Burns then chairman of the Local Government Board. But perhaps we must go further back than Dr McCleary to find the roots of the movement amongst which may well be (1) the rapid fall of the birth rate in France (2) the terrible toll of death from infantile diarrhoea in hot summers especially in 1890 (3) the fact that though preventive medicine had done much to reduce the incidence of disease and the general death rate it had so far done nothing to reduce infantile mortality which stood constant between 100 and 200 per 1000 born according to locality.

MATERNAL MORTALITY

The conference organised by the National Association for the Prevention of Infantile Mortality of which Miss J Halford has been hon secretary since the first conference in 1906 was opened by Sir Kingsley Wood, Minister of Health who spoke on the progress of midwifery practice in Britain during the past five years. He reported the maternal mortality for 1935 as the lowest for five years at 3.81 per 1000 live births. antenatal attention he said is now given to about 60 per cent of pregnant women and the number of women delivered in institutions has risen by 50 per cent since 1932. He referred to the committee he has appointed to inquire into the practice of induced abortion and to the reports recently issued by his department on the so called black areas. A delegate from the United States stated that her country compared favourably with ours in the reduction of child mortality but that the maternal mortality was much higher—about 6 per 1000. It should be borne in mind however that in the States the rate is not computed in exactly the same way as it is here nor is it similar in all the States furnishing returns. Making allowances for differences of casting maternal mortality of England is the lowest of any community speaking our common tongue suggesting that English practice is the best expression of the traditional British approach to midwifery. Our rate is also lower than that of any country with midwifery traditions different from ours with the possible exception of Scandinavia.

¹ Published in *Mother and Child* Lond for June 1937

BACKWARD AREAS

At the first session two papers on welfare work amongst people living in primitive conditions overseas were presented, but not read one by Dr Mary Blacklock, formerly of Sierra Leone, the other by Dr Mabel Brodie, now of Kedah, Malaya, and formerly of Durham county council. The writers spoke upon their papers and dominated the discussion, the most important points of which were the solution of the difficulties of welfare work amongst primitive races where approach must be different from what it is in England, and in places, such as parts of Australia, where populations are sparse and distances enormous. Of special interest were Dr Blacklock's reference to the "hungry season" in Tropical Africa where the natives live mainly by rude agriculture and have recurrent seasons of short rations, often augmented by failure of crops, the obstruction to sound midwifery by tribal customs and religious prejudices and the difficulty of implanting what was best in the European system on what is good, or if not good must be tolerated, of local tradition and practice. It is surprising what progress has been made, especially as in many parts of the Empire the official health service has not the staff to attend to more than the rudiments of sanitary administration.

PROGRESSIVE LEGISLATION

At the second session, which considered progressive legislation in connexion with maternity and child welfare, the chief speakers were Mr R J Howard Roberts of the London County Council and Miss Eleanor Harwarden of South Africa. Two interesting items of the discussion were a plea by Alderman Miss Kellett of Shoreditch for convalescent homes for mothers delivered in their own homes, and another by Councillor Schwann of West Ham for control of factory inspectors by local authorities. The latter is an old contention, somewhat outside child welfare proper, and it was not discussed. Dr Ethel Cassie of Birmingham called attention to the fact that foster children can be dealt with under the maternity and child welfare authority only until they are five years old, after which age they must pass to the public assistance committee which under the Children Acts then take responsibility until the children are nine years old. This matter, now it has been raised, should be capable of adjustment without special legislation. At the same session, Mrs Braddock of Liverpool restated her well known objections to children's courts. Her views, if stated somewhat more softly, would meet with much sympathy.

OTHER TOPICS

Two sessions on the second day were devoted to the education of parents in the care of their children and to nutritional problems in relation to parent and child, Dame Enid Lyons of Australia presiding in the morning and Dr R E Wodehouse, Deputy Minister of Public Health of Canada, in the afternoon. Papers by Dr Eric Pritchard, Dr Ursula Cox, and Mrs Charlesworth (of Northampton Voluntary Infant Welfare Association), Dr Robert McCance, and Dr R Jewesbury, describing situations not unfamiliar to the British section of the audience, were very welcome to the foreign visitors, for they brought out clearly our ordinary everyday English child welfare practice. Here was a case in which much was gained and nothing lost by presenting old matter with no new trimmings.

The last day touched more contentious subjects, psychology in the morning and orthopaedics in the

afternoon. The chairman at the former was Dr J F Gaha, Minister of Health for Tasmania, and at the latter, Dr Josephine Baker, representing the U.S.A. Government. The chief speakers on psychology were Dr Margaret Lowenfeld, hon. director of the Institute of Child Psychology, and Dr J A Hadfield, director of studies at the Tavistock Clinic. Both dealt with maladjustment and its prevention. Prof Helen Koch of Chicago described an experiment in treating asocial children which is being tried with fair success in America. Prevention was the keynote of this session and the net result of the discussion was the impression that lack of parental love was the primary cause of asocial tendencies and neurotic perversions. There was more than a suspicion that over anxiety to avoid the cedipus and electra complexes may lead to the rupture of what might be called the family love bond which ties the generations together and is the base of our social conventions.

At the last session Dr B E Schlesinger (Royal Northern Hospital) spoke of the management of child rheumatism, and Mr E S Evans (Heatherwood Hospital) on general orthopaedics.

CORRESPONDENCE

ADLER AND THE GENERAL PRACTITIONER

To the Editor of THE LANCET

SIR,—May I add one thing to the excellent account of the late Prof. Adler in your issue of June 5th. It has been well said that a number of medical men after meeting Adler seemed to have found something entirely new and satisfying in their medical practice, not just new knowledge but a new outlook and a feeling that what they were doing was really worth while. I should like to corroborate that remark and I think the rapid success of the Medical Society of Individual Psychology which now numbers 127 members, chiefly general practitioners, is evidence of its truth. No one attending those meetings can fail to observe the fresh interest which the Adlerian concept has stimulated in the members and the way in which the very type of case which was most tiresome to them has now become one of the most interesting. In view of the wide prevalence of the minor as well as the major forms of psychoneuroses I think it is clear that Adler's influence will play an important part in increasing the efficiency and helpfulness of general practice.

I am Sir yours faithfully

DIAGNOSIS AND TREATMENT OF GASTRIC AND DUODENAL ULCER

To the Editor of THE LANCET

SIR,—Sir Arthur Hurst's comments on my paper require brief replies—

1 *Carcinoma*.—I used the term relatively uncommon deliberately. One need hardly quote figures to show that one sees 1 case of carcinoma for every 10 or 12 of simple ulcer.

2 *Incidence of gastric and duodenal ulcer*.—Since the general population is composed as to 90 per cent of the "hospital class" it is obvious that there need be no quarrel between Sir Arthur Hurst and myself on this score. Possibly the eminent writers of text books have taken their figures exclusively from their rich patients. But I am still inclined to think that surgical experience determined the usually quoted figures of 4 duodenal to each gastric ulcer.

3 *Blood in stools*.—I specified the benzidine reaction. The spectroscope was not used nor do I see the value of it in this connexion. One requires a test with a certain threshold very much as the Fehling reaction is designed to ignore the normal 100 mg per 100 c.c.m. of glucose in urine. The tests were performed by the biochemical laboratory of the hospital under the direction of Mr F. Morton B.Sc. A.I.C. I cannot see that other statements made by Sir Arthur under this heading contradict anything written in my paper.

4 *Diagnosis*.—Sir Arthur has quoted from my paper in a way that has misrepresented what I said which was that while iron deficiency was the most likely cause of anaemia with achlorhydria it was safest to assume that ulcer was present until proof to the contrary was forthcoming by negative stool tests, absence of blood from test meal and negative radiogram. I also as stated in my paper have not seen achlorhydria with duodenal ulcer. My incidence of achlorhydria with gastric ulcer was 2 in 39. Sir Arthur's is 1 in 114. No doubt if one accumulated

several hundred cases the true incidence would be found but I would not be particularly concerned if it were proved that I were wrong and that achlorhydria does not occur in gastric ulcer. Faber and others have shown that 'gastritis' with diminished acidity is the usual forerunner of ulcer whether acid is absent or only just present probably depends merely on the number of functioning cells remaining.

5 Sir Arthur gives no reasons for his advocacy of surgery. I remain convinced, as stated in the paper that beyond perforation, surgery is only justifiable for gross anatomical deformities which make life intolerable and which are unaffected by some months of medical treatment.

I am Sir yours faithfully

Birmingham June 5th.

DUNCAN LEYS

INFECTION THROUGH THE OLFACATORY MUCOSA

To the Editor of THE LANCET

SIR,—Not being a chemist by training I am diffident of entering too deeply into what may be a purely chemical controversy nevertheless I believe that Dr. Pickworth's letter in your issue of May 1st merits some reply.

When our work was begun I was of Dr. Pickworth's opinion that we were using a chemical solution. However we soon discovered that no matter what the origin of the many samples of potassium ferrocyanide and iron ammonium citrate we used when equal volumes of 10 per cent. solution of these two chemicals are mixed granules and aggregates of granules are formed. On first mixing the fluid remains clear but after a few seconds turns cloudy. If this change be followed under the microscope it will be seen that the clouding is due to a formation of particles (singly or in aggregates) throughout the fluid. The particles vary in size but many are about 0.2 micron in diameter which is of the same order of magnitude as the prussian blue particles demonstrable in the tissues after fixation and only slightly smaller than pneumococci. They can be thrown out of suspension in an angle centrifuge quite an appreciable amount being deposited in 15 minutes at 3500 r.p.m. We have also noted that the formation of these particles is brought about in part by visible wave lengths at the blue end of the spectrum actually by those waves shorter than 5000 Å. Any mixing of the two solutions by daylight will certainly cause the particles to form moreover we have been unable to prevent the formation of particles albeit in smaller numbers even by carrying out the manipulations in the dark room.

As to the chemical nature of the particles or granules used I believe that they are prussian blue. My belief is based largely on the personal assurance given me by many expert chemists. Perhaps also I may be allowed to quote from Mellor (*Modern Inorganic Chemistry* 8th edition London 1936) he says that prussian blue is formed when a solution of potassium ferrocyanide is added to a solution of a ferric salt. It is insoluble in hydrochloric acid but soluble in oxalic acid forming a deep blue solution. Besides the insoluble prussian blue a soluble or colloidal prussian blue is formed when a ferric salt is added to a solution of potassium ferrocyanide or a ferrous salt to a solution of potassium ferri-cyanide. By the addition of salt to the solution the soluble prussian blue is coagulated or salted out and the

precipitate is then 'insoluble' Prussian blue" (The italics and inverted commas are Mellor's)

It will be clear to Dr Pickworth, I hope, that if I have misinterpreted Le Gros Clark I have done so not because of mere assumption on my part, but because our investigations had led to the belief that Clark was using a suspension of particles. Indeed it is difficult for me to believe that he did not, despite Dr Pickworth's statements to the contrary. I must, however, take this opportunity of thanking Dr Pickworth for again drawing my attention to this point and leading me to study the matter further. Since reading his letter I have reinvestigated most of the former work and have taken the further step of testing the behaviour of our mixture of potassium ferrocyanide and iron ammonium citrate when subjected to ultra filtration through a Cellophane membrane. This has shown that soluble prussian blue in our mixture will pass through membranes which hold back serum proteins. It would seem, therefore, from this most recent work that, in actual fact, we are dealing with a suspension of prussian blue particles in a solution of prussian blue. Any further information which Dr Pickworth has on the point would be most welcome.

Finally, even leaving the "supposed passage of particles" out of the question, I cannot agree with Dr Pickworth that I used bacteriological methods only. Surely he does not consider the direct microscopical demonstration of pneumococci in the perineural spaces, in the subarachnoid space, and in the cells of the pia mater within two minutes of their being instilled into the nose a bacteriological method only.

I am, Sir, yours faithfully,

G W RAKE

Connaught Laboratories, University of Toronto
Canada, May 26th

MIDDLE-EAR DISEASE

To the Editor of THE LANCET

SIR,—Otitis media is of perennial interest to general practitioners, and your weighty remarks thereon prompt me to record the following experience. At the end of 1930 I treated for a long time a man with the most profuse and persistent otorrhoea I can remember, and by the irony of fate it followed on the only paracentesis I had ever performed—I believe quite correctly. In despair he asked me to try anything short of operation so after some months I one day washed out his ear with staphylococcus antiviral liquid and left some of the fluid in situ. The result was dramatic, for he failed to come again as instructed, and when, after six days, I searched him out he said he was cured. Actually he had had no discharge for three days and only a slight dampness since. After a few more treatments his ear was quite dry and has remained so.

This was, I believe, the first such case ever treated in this way and it was certainly the start of the fairly widely adopted treatment of otitis media by antiviral preparations (not that all cases respond so rapidly as he did). It is, unfortunately, often considered unscientific because it is said to lack a sound theoretical basis, but surely the scientific attitude is to observe and try to appreciate results and then seek to find the underlying theory. Whatever the rationale of the method may be, I know of no more convincing demonstration of the potency of a biological preparation than to watch the extraordinary way it will determine improvement in a few hours in an inflamed, and even bulging, ear drum, which may return to normal within two or three days.

One of my earliest cases was that of my own little son, aged three, who for a whole day had been crying with earache while I tried the effect of one after another of the ordinary and proprietary preparations without avail. To watch him settle down to a quiet sleep within half an hour of instilling the antiviral was one of the most gratifying experiences of twenty odd years' practice, and it has been no less satisfactory to hear of similar results in nearly every case of earache I have treated in this way since. Later on, at my suggestion, antiviral was put up in a jelly form which is much easier to use in these cases and gives results almost equally good.

Where the issues are so serious I would not like to seem to say a word against the operation of paracentesis, but I would like to urge that practitioners and otologists alike should carry a tube of antiviral jelly in their bags, and that they should instil some as soon as they have had a good look at the tympanum. They can then make preparations for paracentesis if they wish, but unless my almost consistent experience is exceptional they will usually find that in a short time the pain will have gone and the need for operation will have passed. What the effect would be in the so-called silent cases or tuberculous ones I do not know, nor do I prophesy, but I am sure that it is a line of treatment abundantly worth trying.

I am, Sir, yours faithfully,

Winsford, Cheshire, May 29th

W N LEAK

LEFT INFRAMAMMARY PAIN

To the Editor of THE LANCET

SIR,—I read with much interest the article on this subject in your issue of May 29th by Drs Shirley Smith, Stephen Hall, and Jocelyn Patterson, especially on "the disturbance of the heart muscle either from lack of sugar supply or inability to metabolise sugar." Having had a large experience of such cases in hospital and private practice I would like to refer to the more common causes of this pain and effective methods for its relief. Exposure of the chest to cold, physical fatigue, and a rheumatic temperament are among the many causes of this trouble. Treatment after consideration of the history, occupation, and temperament and a thorough examination of the heart and circulation have been made with a negative result, the probability is that the intercostal muscles are affected and that rest is the more hopeful method of giving relief. I have several strips of plaster about 1½ in wide of sufficient length to extend from the spine to the middle of the chest in front. If possible the patient stands erect steadying his body by holding his hand to a mantelpiece, the plaster is first fixed on the spine and firmly brought round the side of the chest. Three or four strips are generally sufficient. The effect is sometimes quite dramatic. For the next few days treatment of the possible cause is carried on. If after removal of the strips the pain remains the treatment is repeated. At times a dull ache remains, when a liniment containing menthol and methyl salicylate will complete the cure.

I am, Sir, yours faithfully,

CHARLES W CHAPMAN

Wimpole street W June 5th

METHODS OF DESTROYING BED BUGS

To the Editor of THE LANCET

SIR,—In your issue of May 1st Mr J M Holborn makes certain criticisms of the use of heavy coal tar naphtha for the destruction of bed bugs, according to the method we described (*Lancet*, Feb 27th, 1937,

p 530) To these criticisms we offer the following reply:—

(1) *Toxicity to insects*.—To ensure a 100 per cent kill of both insects and eggs at a temperature of 65–70° F an exposure of at least 18 hours is necessary and we are not surprised at the poor results obtained by Mr Holborn in an experiment using an exposure of only 6 hours.

(2) *Toxicity to man and animals*.—Naphtha vapour has an irritant action on the eyes and for this reason gas masks are worn during fumigation. The specification framed to govern the supply of naphtha makes no attempt to ensure the absence of mesitylene. A proportion of this together with its isomer pseudocumene is present; but from the results of an extensive series of toxicity experiments with animals we are satisfied that danger to man from this constituent or the naphtha in its entirety is not to be apprehended.

(3) *Fire and explosion risk*.—While all reasonable care must be exercised when naphtha is being handled or sprayed we are of opinion that the concentration of vapour which might be expected to leak into adjoining premises would not inflame when brought into contact with a naked light. In regard to explosion risk the vapour concentration at 65° F is only one-eighth of the lowest explosive concentration.

(4) *Odour*.—The odour of naphtha vapour is penetrating but not unpleasant and few complaints have been received from the occupants of adjoining houses.

We should like to emphasise that whilst naphtha is also a contact insecticide it is the lethal property of the vapour which makes it so efficacious for the destruction of bed bugs in infested houses. Since our original publication we have improved the technique of distributing the vapour in rooms by the use of blankets wetted with naphtha and sus-

pended near the ceiling and down the walls. In this way all likely harbourages including ceiling cracks will receive a lethal concentration of vapour. Mr Holborn points out that the quantity of naphtha used is ten times the lethal dose and it may be stated that this amount is necessary to allow for loss of vapour through diffusion absorption and air changes.

Mr Holborn, and later Mr Mellanby indicate the possibilities of contact insecticides for use in occupied houses. Such measures are helpful in dealing with a light infestation but in our opinion a heavy infestation can only be dealt with successfully by a fumigation process. The premises must be vacated but the furniture can be treated in situ with heavy naphtha. Experiments have been carried out which promise well for the use of heavy naphtha for van fumigation and further research in this direction is in progress.

We agree as to the desirability of knowing the nature and amounts of the toxic constituents and would point out that research into this question is in hand. If and when this information is available it must not be forgotten that the isolation of the lethal constituent or constituents would give a product of greatly increased price and unless possessed of exceptional properties this would hardly be expected to replace naphtha for practical fumigation purposes.

We are Sir yours faithfully

OBITUARY

WILLIAM FRYER HARVEY M.B. Oxon

Dr W. F. Harvey who died on June 4th at his home in Letchworth at the age of 52 was an Oxford medical graduate qualifying belatedly in 1917 after a period of ill health. But his chosen profession early surrendered him to letters where his heart was from the beginning. One of a family of seven brothers and sisters in a household full of intellectual stimulus he was always reading widely and devoutly and even as a child was rarely to be seen without a pencil in his hand. His book entitled 'We were Seven' which appeared less than a year ago contains a series of contemporaneous pictures of his youth for he was able apparently in writing it to reproduce his own feelings at the time of the happenings so that the book is neither a biography nor a psychological study but is an inquiry into the mind of the child in a happy family circle. Not that he lacked the faculty of judging—parenthood as is evident to those who noted his initials at the foot of a bogus report of the Hampstead branch of the Parent Study Association (*Lancet* May 6th 1933) when the problem parent was submitted to careful analysis and yet kindly analysis for Harvey a great interest was in the foibles of good people and as a satirist of the Society of Friends to which he belonged he did it a valuable service. Accounts of his life in the daily press have laid stress on an act of heroism when he was surgeon lieutenant in the Navy and completed an amputation on a wounded fellow officer in the engine room of a sinking destroyer for this act he was awarded the high distinction of the Albert medal but the incident almost escaped record because Harvey forgot about it himself taking it simply in his stride as part of

war time medical work. Pacific himself in thought and in practice he was always unwilling to accept security at the expense of others' danger and hazard.

Dr Harvey married Miss Margaret Henderson. He leaves two children a boy and a girl.

CHARLES H. SHORNEY WEBB, M.S. Lond F.R.C.S. Eng.

On June 1st Mr Shorney Webb died of infective endocarditis in the Middlesex Hospital where he received his medical education and where for a dozen years before the breakdown that crippled his life he had been a brilliant member of the honorary surgical staff. Webb writes a former surgical colleague had a fine academic career gaining honours and distinctions not only in the Middlesex school but also in the University of London; he was only the fourth Middlesex student to secure the M.S. degree and obtained marks qualifying for the gold medal on that occasion. During his tenure of a surgical readership at the hospital the wanderlust seized him and he served in the Balkan campaign of 1912. In 1914 the first day of the late war saw him eager alike for adventure and to place his talents at the disposal of the British wounded. Webb landed in the original Expeditionary Force with the fourth casualty clearing station a unit with which he remained until 1918 when he was appointed to the charge of a surgical division of the 24th general hospital at Etaples. At a time when opinion was still divided as to the desirability of exploration for gunshot wounds of the abdomen he was one of the first to operate for this type of injury. To Owen Richard of course belongs the credit of demonstrating and of urging the need of surgery in these particular

wounds of warfare, but the first considerable communication dealing with the subject was written by Webb and Milligan.

Elected in absentia to the honorary staff of his old hospital during the war years, he did not assume his duties until after the armistice. Possessed of a far greater operative experience than usually belongs to a newly appointed assistant surgeon, Webb proved himself also a fine teacher, acquiring a popularity with the students akin to that which he had enjoyed among his colleagues in his early days and in France, while his surgical advice and services were sought by his colleagues and their families. And later,

when he was again able to lead an active life, he became a valued operating surgeon to the Middlesex county council.

Webb's gifts were many. He was a fine linguist, a lover of music, he played piano and organ, he loved churches and old ecclesiastical architecture, and the memory may still linger in the minds of his war comrades of the strains of some church organ, by strange caprice intact, pealing forth from a ruined church without roof, with walls wide open to the air, an anthem perchance strange to the rude ears of that time, and within a debonair surgeon playing intently and with an exquisite skill.

G G T

PUBLIC HEALTH

The New Scottish Maternity Services

THIS week local authorities of Scotland have been called upon to submit schemes under the Maternity Services (Scotland) Act, 1937, which came into operation on May 16th. The schemes must secure that there are available to every woman who is to be confined in her own home and who applies to the local authority, facilities for—

(a) the services of a certified midwife before and during childbirth and until the end of the lying-in period,

(b) medical examination and treatment during pregnancy, including at least three prenatal examinations,

(c) medical supervision during childbirth and the lying-in period,

(d) medical examination at least once after the expiry of one month after childbirth

(e) the services of an anaesthetist when recommended by the medical practitioner, and

(f) the services of an obstetrician where necessary and practicable

The general object of the Act is to provide, for women who are to be confined in their own homes, care and treatment based on the team work of doctor, midwife, and consultant. This is a much wider object than that of the English Act of last year, which provided only for a service of midwives. The maternal death rate is much higher in Scotland than in England and the conditions of midwifery practice are different, doctors engaging in it to a greater extent. A Government grant, equivalent to half the additional expenditure involved but scaled up or down according to the needs of the area, will be payable on the new schemes. Fees will be paid by the women in so far as they are able to pay, but no charges will be made to the necessitous, and insured women, the wives of insured men, and others in like economic circumstances are likely to obtain the whole range of services for an inclusive fee that will be little, if at all, more than they pay at present for a midwife alone. Local authorities are asked to aim at giving the women as wide a choice as is practicable of doctor and midwife. Though they must provide the services specified in the Act, they will have a fairly free hand in the actual arrangements they may make. Thus they may arrange to have the midwifery service provided through voluntary associations or they may themselves pay midwives in private practice on a fee basis, or they may employ a whole time salaried staff of midwives. As regards the medical services, the Department suggest that probably most authorities will throw this service open to all general practitioners who desire to take part in it. The Department, however, will be prepared to consider alternative proposals. The remuneration of the doctors to be employed is under discussion.

Consulting obstetricians, the Department say should be obtainable in the four teaching centres and surrounding areas and in places where maternity hospitals employing resident obstetricians have been established. "If obstetrical specialists are made widely available throughout Scotland, a great step will have been taken towards raising the standard of domiciliary midwifery. Accordingly, the Department will expect local authorities to make every reasonable effort to overcome any difficulties with which they may be faced" in obtaining this expert service.

Compensation will be paid to midwives who, within a specified period, surrender their certificates either voluntarily or by direction of the local authority. Half the cost of this compensation will be refunded by the State.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 20TH, 1937

Notifications—The following cases of infectious disease were notified during the week: Small pox, 0; scarlet fever, 1477; diphtheria, 910; enteric fever, 28; pneumonia (primary or influenzal), 765; puerperal fever, 39; puerperal pyrexia, 138; cerebro-spinal fever, 24; acute poliomyelitis, 9; polio-encephalitis, 1; encephalitis lethargica, 5; continued fever, 1 (St. Pancras); dysentery, 26; ophthalmia neonatorum, 94. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on June 14th was 2918 which included: Scarlet fever 750; diphtheria 813; measles 51; whooping-cough 485; puerperal fever 23 mothers (plus 14 babies); encephalitis lethargica 282; poliomyelitis 1. At St. Margaret's Hospital there were 27 babies (plus 18 mothers) with ophthalmia neonatorum.

Deaths—In 123 great towns, including London there was no death from small pox, 2 (0) from enteric fever, 10 (0) from measles, 4 (1) from scarlet fever, 11 (4) from whooping cough, 25 (4) from diphtheria, 60 (15) from diarrhoea and enteritis under two years, and 22 (5) from influenza. The figures in parentheses are those for London itself.

Tottenham and Nottingham each had one death from enteric fever. Birmingham 3 deaths from measles. There were 3 fatal cases of diarrhoea at Croydon, Liverpool, Birmingham, and Stoke-on-Trent.

The number of stillbirths notified during the week was 307 (corresponding to a rate of 30 per 1000 total births), including 41 in London.

CENTENARY OF CARDIFF ROYAL INFIRMARY—During last week as part of the centenary appeal of this hospital for £250,000 a special service was held at St. John's Church and a centenary commemoration dinner at the City Hall, at which Lord Horder was the principal guest. On June 6th Lord Dawson broadcast an appeal for the hospital on the National Programme.

University College Hospital

Men students of University College Hospital who have held a resident appointment there are invited to apply for a Bilton Pollard fellowship of an annual value of £850. Further particulars will be found in our advertisement columns.

London Hospital

The King has consented to become patron of this hospital. Queen Mary will continue to hold the office of president. As a memorial to the late Sir Ernest Morris, it is proposed to extend the clinical laboratories, towards the cost of which he had collected £3000.

St Bartholomew's Hospital

Particulars are given in the Medical Diary in another column of a post graduate course which will be held at this hospital on June 17th, 18th, and 19th. The course is open to all medical men but early application should be made to the dean of the hospital.

Pharmaceutical Society of Great Britain

At the June council meeting Mr Thomas Marns was re-elected president, Mr E T Neathercoat was re-elected treasurer, and Mr Thomas Guthrie was elected vice-president. Mr J H Franklin was co-opted a member of the council to fill the vacancy caused by the death of Mr E H Simmons.

Joint Tuberculosis Council

At the May meeting it was announced that 750 copies of the Council's memo on Tuberculosis Among Nurses had been printed and that the Medical Research Council were considering the republication of the memos by Drs W H Tytler and Peter Edwards on The Microscopic and Cultural Examination of Sputum. After a discussion on the Empire Conference on the Care and After Care of the Tuberculous it was decided to form a committee—comprising Dr S Vere Pearson (convener), Profs W W Jameson and S Lyle Cummins, with Drs Jane Walker, J B McDougall, F R G Heaf, and F W Goodbody—to consider what help this council can give the colonies in their effort to control tuberculosis. The question of holidays with pay was placed on the agenda for the next meeting.

Medical Tour to Russia

The Society for Cultural Relations is this year again organising a tour for medical visitors to the Soviet Union. The group will leave London on July 17th and visits will be paid to Leningrad, Moscow, Kharkov, and Kiev. They will return to London on August 8th. Opportunities will be given to members to visit hospitals, dispensaries attached to factories, venereal disease clinics, and prophylactoria (preventive clinics). A member of the society's medical and public health section will lead the group, and if possible arrangements will be made for members to see any specialised branch of medicine in which they are interested. Further information may be had from the secretary of the society, 98, Gower street, London, W C 1.

Fellowship of Medicine and Post-Graduate Medical Association

An all day course in gynaecology will take place at the Chelsea Hospital for Women from June 14th to June 26th. Courses have been arranged for M.R.C.P. candidates in neurology at the West End Hospital for Nervous Diseases, in the afternoon (June 21st to July 3rd), in tuberculosis at Preston Hall, Maidstone, on July 3rd. Other courses will be held in proctology at St Mark's Hospital (July 5th to 10th), in dermatology at the Hospital for Diseases of the Skin, Blackfriars (afternoons July 12th to 24th), in urology, at All Saints Hospital (afternoons, July 12th to 31st). Week-end courses will be given in general surgery at the Prince of Wales's Hospital (June 19th and 20th), in diseases of the heart and lungs at the London Chest Hospital, Victoria Park (July 3rd and 4th), in medicine and surgery at the Miller General Hospital (July 10th and 11th). Courses are open only to members and full particulars may be had from the secretary of the Fellowship, 1 Wimpole street, London, W 1.

St Thomas's Hospital

On Tuesday, June 29th at 3 P.M., Sir Farquhar Buzzard, regius professor of medicine in the University of Oxford, will distribute the prizes at this hospital.

Birmingham Hospitals Centre

It is thought that a portion of this great centre may be open next spring. The foundation stone was laid in October, 1934. The first part of the scheme comprises a general hospital of 500 beds complete with all services a nurses' home, and the medical school buildings. The nurses' home will accommodate 350.

A Fever Hospital in Spain

In view of the increasing danger of epidemics in Spain the Holborn and West Central London Committee for Spanish Medical Aid (8, Gordon square, W C 1) was asked a month ago to provide a bacteriologist and equipment for a fever hospital on the Madrid front. Within a fortnight it had sent out to Valencia a doctor, a bacteriologist, and an assistant, with enough material for a small laboratory. An hotel has been taken over at Cuenca 70 miles from Madrid, which will hold 150–200 patients, but it lacks equipment. Beds, bedding, and linen can be bought cheaply in Spain, and money for this is urgently needed. The initial outlay was £300, and the bacteriologist has now called for a further £200 for buying additional equipment in Spain. The committee is at present able to send only £50 and is trying to raise the further £150 within a week.

Prostitution and Venereal Disease

The International Abolitionist Federation held a congress in Paris from May 20th to 22nd, when a number of delegates, both French and foreign, paid tribute to the Minister for Public Health, M. Henri Sellier, for taking responsibility for the first Bill introduced by a French Government which forbids traffic in women in all its manifestations. After hearing reports from Dr Hermans (Holland), Prof Gemählung (France), and Miss Alison Neilans (general secretary of the Association for Moral and Social Hygiene) the congress adopted resolutions pointing out that prostitution cannot in itself constitute a punishable offence but that public authorities cannot be indifferent to its public manifestations. The measures adopted to stop street solicitation must be applied to men as well as to women, their enforcement should be entrusted to the common law police and must not be arbitrary. A service of women police should be everywhere established with the special duty of assuring the protection of children and to give assistance to women who need their help. The rôle of the law, in combating prostitution, should consist, above all, in forbidding procuration in all its forms. The modern struggle against venereal diseases must be based on liberty, treatment must be voluntary, free, and confidential, and it is unjustifiable to impose coercive measures on certain sections of the population.

Appointments

BORD, M R E M B Dubl. Lady Resident Medical Officer at the Ilford Maternity Home.
 CRAIG, JENNY D M B Manch. Assistant School Medical Officer for Huddersfield.
 DINGOLE, W S M Ch Orth Liverp. F.R.C.S. Eng. Hon. Orthopaedic Surgeon to the Bootle General Hospital.
 FLEMING, H T M B Dubl. F.R.C.S. Eng. and Irel. Surgeon Superintendent at the Fermanagh County Hospital Enniskillen.
 GRAY, S T G M B Aberd. D.P.H. Assistant County Medical Officer and Assistant School Medical Officer for West Suffolk.
 MCGUCKIN, FRANCIS M D Durh. F.R.C.S. Edin. Hon. Assistant to the Throat and Ear Department of the Royal Victoria Infirmary, Newcastle-upon-Tyne.
 RICKOW, A V M B Lond. D.M.R.E. Hon. Radiologist to the Princess Louise Kensington Hospital for Children.
 ROSE, I. M B Leeds. Resident Medical Officer at the St Helen General Hospital, Barnsley.
 SAINT, J H M D Durh. M.S. Minn. F.R.C.S. Eng. F.A.C.S. Hon. Assistant Surgeon to the Royal Victoria Infirmary, Newcastle-upon-Tyne.
 SCHOLEFIELD, JOHN M B Leeds. F.R.C.S. Eng. Resident Surgical Officer at the Prince of Wales's Hospital, Plymouth.
 Certifying Surgeon under the Factory and Workshop Acts: Dr J L HILL (Newport District, Monmouth) Dr J S Moore (St Austell District, Cornwall).

PARLIAMENTARY INTELLIGENCE

HEALTH AND HOUSING

In committee of the House of Commons on June 8th on a supply vote for the Ministry of Health, Sir KINGSLEY WOOD, Minister of Health, said that the estimates for health services amounted to over £22,000,000 and the total for all the departmental services reached £108,000,000. There was an increase of over £500,000 compared with the current year. The slum clearance campaign was responsible for an additional sum of £500,000 in respect of new houses and a new item in the estimates was £207,000 for grants under the Midwives Act which would come into operation in a few weeks. Considerable activity had been displayed by local authorities in the provision and extension of sewers and the disposal of sewage, and there had been increased provision for public recreation. In 1920 the total amount of loans for public recreation was £1,260,000; last year it was £3,200,000.

THE PUBLIC HEALTH BALANCE-SHEET

Taking the credit side of the public health balance-sheet he could say that motherhood was safer than it had been for 18 years, inasmuch as maternal mortality for every 1000 live births was the lowest recorded since 1922. The tuberculosis death rate continued to decline and there had been a steady decline in mortality from infectious disease. There had also been a substantial decrease in the prevalence of diphtheria. There was however another side to the balance sheet—cancer. While many more lives were now being saved by early diagnosis of the disease, cancer remained one of the most deadly enemies of mankind and was the single heaviest item on the debit side of the national health balance-sheet. Colds and influenza still accounted for nearly a quarter of the absences from work in this country, and while it was true that last year's influenza epidemic was what was called clinically mild, he could assure the committee on the best authority that there was not likely to be a further visitation on the same scale for two years.

MOVEMENTS OF POPULATION

The estimated mid-year population in 1930 of England and Wales was 40,830,000, an increase of 101,000 over the estimated mid-year population figure for 1935. The total number of births was 605,202, the birth rate per 1000 living being 14.8 or 0.1 per cent. higher than for 1935 and 0.1 above that of 1933, the lowest on record in this country. There were 405,704 deaths and the crude death rate per 1000 of the population was 12.1. This was 0.4 per 1000 higher than in 1935 and 0.7 above that of 1930, the lowest on record. The problem of population in this country was engaging increasing public attention and was a vital matter. Certain facts were already known in connection with it but before they could properly consider it they would certainly need to know many more. The birth rate, which in 1877 was 35.1 per 1000 living had now fallen to 14.8. It was told that to-day mothers had about half the number of children which their grandmothers had and they knew for instance, that in the next 15 years the total number of children aged five and over in public elementary schools might fall by as much as 1,000,000. The population in the immediate future would contain a much larger proportion of older people. They could not of course say if all those conditions would continue; it was not necessary to be pessimistic about the matter as to whether for instance they would have to take into account a stationary or a declining population. Two inquiries were in progress on this matter, one by the Registrar-General and the other by the Population Investigation Committee, a voluntary body under the chairmanship of Prof. Carr-Saunders. There was close co-operation between the two inquiries.

The present methods of obtaining and keeping important vital statistics concerning this matter were unsatisfactory and incomplete and further information was undoubtedly necessary in connexion with fertility. The existing birth rate statistics showed the number of children born in the population as a whole but fertility statistics must relate to births of particular parents and show the kind of parents and in what conditions they produced many or few children. Other particulars required were the ages of the parents, the duration of the marriage, the date and order of the births, and matters of that kind. If those facts were available it would be possible to investigate much more adequately the conditions and circumstances which appeared to encourage or discourage the production of children. He was considering the best steps that could be taken to see that these particulars were procured with due regard to their confidential and personal nature.

BUILDING PROGRAMME

There had been a record total in house building with the erection of some 318,000 houses compared with 325,000 last year and 329,000 in 1934-35. Rural housing presented its own special problems and rural district councils were now concentrating on slum clearance and their original programmes had been increased by approximately two-thirds. The present programme covered some 55,000 houses of which nearly 23,000 were to be dealt with under clearance orders. He had asked the central advisory council to consider further steps so far as rural housing was concerned. He hoped to receive a report soon and would then consider what further action might be necessary in the light of the report. He would ask the House to approve at a later date the extension of the present rate of subsidy both for slum clearance and for the abatement of overcrowding so as to apply it to houses completed up to Dec 31st 1938.

NOTES ON CURRENT TOPICS

Milk supply and Animal Diseases

On June 7th in committee of the House of Commons, on a vote for the Ministry of Agriculture, the Minister Mr. W. S. MORRISON said that the milk scheme had so far rendered possible a start on the great question of improving the quality and increasing the consumption of this vital food. In the last financial year the amount of milk sold in the liquid market increased by 14,500,000 gallons and the quantity for manufacture had increased by 8,000,000 gallons. There had been an immense increase in the number of persons producing milk which reached an accredited standard. Before the scheme was introduced there were only 800 Grade A licences but now there were nearly 20,000 producers of milk of accredited standard.

With regard to poultry disease the technical committee which had been set up was considering the present methods of distribution of hatching eggs, day-old chicks, and feeding stuffs. Strenuous efforts were being made to lessen the toll of mortality among the chickens. The utmost research into the pathology of diseases which had caused the losses among poultry was being continued by the scientific bodies concerned. Any further measures which might be taken would be of an administrative character when the new central veterinary service came into being. Referring to the immense burden of animal diseases which cost the industry something like £11,000,000 a year, the right hon. gentleman said that a great deal of work had been done in the past by local authorities and by the Ministry's veterinary service and practical results had been obtained. During the last financial year there were 13 centres of infection from foot and mouth disease and these comprised 60 separate premises. The policy which had been carried out had had the result that the disease had not become

endemic in this country, as it had in some of our continental neighbours. It could be regarded as a hopeful sign that the incidence of this disease on the Continent seemed to be declining. There was a slight increase in the incidence of anthrax, but a satisfactory decrease in swine fever and sheep scab. There were still diseases like tuberculosis, contagious abortion, mastitis, and others which took an immense toll of our cattle. The proposals which he had recently announced would involve legislation and represented a very much bigger step forward and a much more resolute attack on this problem than had yet been made. He hoped, with the cooperation of those concerned, that it would yield substantial results in freeing the industry from a wasteful burden.

Replying to the debate which followed, Mr Morrison said that the Ministry of Agriculture had under investigation a diagnosis by which it might be possible to detect John's disease in its early stages and not only effect a cure but prevent infection. This was being tried out, and they hoped in a short time to know whether it was a good thing or not.

Some Colonial Health Problems

In the House of Commons on June 2nd on a Colonial Office vote Mr Ormsby Gore, Secretary of State for the Colonies, referred to social conditions in Hong-Kong and the Straits Settlements. The reports, both majority and minority, of the mu-tsai question had, he said, been sent to the governors of these two colonies asking for their considered views. In both colonies the predominant element was a shifting Chinese population among which for centuries there had been social customs repugnant to British ideas. The British Government has set its hand to eradicate or mitigate the evils from these customs and was not going to turn back. But despite all its efforts mu-tsai and other customs went on, and devices such as adoption were resorted to in order to get round the law. There was, however, a growing public opinion of a more Western character and it was essential for real success to carry the Chinese population with them.

Mr LUNN said there was no method of dealing with the buying and selling of human beings except by total abolition. He went on to deplore the conditions of health in the West Indies, where malaria and typhoid were common, food was poor and lacking in nutritive value, sanitation was bad, people were living in overcrowded conditions, wages were low, and unemployment rife.

Mr DE ROZSCHILD recalled an investigation made by the Ross Institute showing that on the seial estates in East Africa the work performed by native labourers was only a sixth of the value of that done by Malayan labourers. This could be attributed to defective sanitation, lack of malarial control, poor nutrition, and bad working conditions in general.

Miss HORSBROUGH said while they could not abolish the system of mu-tsai all at once, there should be immediate notification of the transfer of children under the age of 12 and a register of all who were living away from their family, up to the age of 16 or 18.

Sir ERNEST GRAHAM-LITTLE compared the state of hygiene in East Africa with that on the West Coast, where the land was largely held by the natives. In Kenya the density of population in the native reserves, up to 250 to the square mile, exceeded that in British India. Most unfortunate was the inability of the native to pay the land tax in Nyasaland, where 50 per cent of the adult males had left the district to work in other parts of British Africa and the tribal system had broken up. He went on to compare health conditions among the Masai and the Kikuyu whose diet had weakened their resistance to disease, and to cite the alarming incidence of disease in certain parts of Kenya, where climatic conditions were favourable and venereal disease infrequent but anaemia, malnutrition, yaws, pyorrhea, malaria, hookworm, and tuberculosis were rife. These

were preventable diseases and it was a grave indictment against British rule for preventable diseases to prevail on this scale. The primary difficulty might be lack of funds but the research laboratory in Nairobi provided pathological data which would cost at the ordinary price over £20,000 a year. He hoped it would be possible for the Colonial Office to provide further assistance for medical research.

Mr SORESENSEN noted the decline in physical well-being of the natives mentioned in recent reports from the Gold Coast, where the medical staff had declined and less personal attention could be given. In 1929, he said, 90 medical officers attended to 250,000 patients, whereas in 1935 there were only 66 medical officers for 273,000 patients. There was a shortage of staff for the treatment of leprosy and nothing being done to investigate the incidence of silicosis and tuberculosis. A class of native capitalists now growing up unaccustomed to stringent public health and other restrictions might easily create conditions in which ill health was bred. He understood that only 10 per cent of the children of school age were receiving education.

Mr ORMSBY-GORE, replying to the debate, claimed that on the whole conditions were better in the British colonial empire than in any other, and that remarkable progress had been made in the last ten or fifteen years. Before incurring expenditure for medical research he must take advice from the Medical Research Council. The causes of most tropical diseases were known, the only way to deal with malaria was to kill the mosquitoes, and remarkable work in controlling yaws was being done by the British medical staff all over Africa.

On June 8th, in the House of Lords, the Widows', Orphans', and Old Age Contributory Pensions (Voluntary Contributors) Bill passed through Committee. The Poor's Allotments in Walton upon-Thames Bill was read the third time, and passed.

QUESTION TIME

WEDNESDAY, JUNE 2ND

Eradication of Animal Diseases

Mr HENDERSON STEWART asked the Minister of Agriculture if any provision was being made in his long-term policy for the eradication of disease in livestock, for reducing the mortality caused by grass sickness in horses, disease in poultry, and swine fever among pigs. Mr RAMSBOTHAM replied: The Government's policy for the eradication of disease in livestock which my right hon friend announced last Thursday, will extend, as circumstances permit, to all classes of farm animals, including poultry, although efforts will be mainly directed in the first instance to the eradication of disease among cattle. It is impracticable, in the present state of knowledge, to recommend immediate measures for reducing the mortality caused by grass sickness in horses. As regards poultry diseases my right hon friend is considering what steps can usefully be taken pending the report of the Technical Committee which is examining methods of distribution of breeding stock, hatching eggs, and day old chicks, with particular reference to mortality. The policy now in force for the control of swine fever will continue. Research in all matters is being actively pursued under the auspices of the Agricultural Research Council in collaboration with the Agricultural Departments.

THURSDAY, JUNE 3RD

Drunkenness in London during Coronation Week

Sir ALFRED BETT asked the Home Secretary the number of persons arrested for being drunk and disorderly in the County of London during Coronation week, and the number so arrested during the corresponding week of 1936. Sir SAMUEL HOARE replied: I regret that the particulars asked for by my hon friend could not be

extracted without a considerable expenditure of time and labour. I can, however, inform him that the number of persons charged with drunkenness of all kinds in the whole Metropolitan police district during Coronation week was 49. The figures for the corresponding week in 1936 are not available but the figure for the week preceding Coronation week was 405.

Watered Milk

Mr JENKINS asked the Minister of Health if his attention had been called to the report of the analyst for the county of Monmouthshire in which it was stated that the composition of a large number of milk samples was highly unsatisfactory as in a number of cases a large percentage of water had been added and in other cases the amount of fat removed was extremely high and what steps he proposed to take to ensure to the public that milk available for sale should be of the highest quality and free from adulteration.—Sir KINGSLEY WOOD replied: My attention had been called to this report and I am in communication with the county council in the matter.

MONDAY JUNE 7TH

Ventilation of the House of Commons

Mr BOSCH asked the First Commissioner of Works whether seeing the great advances made in recent years in the science of ventilation he would cause an investigation to be made to ascertain if the ventilation of this chamber could be made more satisfactory during the recess this summer.—Sir PHILIP SARGISON replied: I will send my hon. friend a copy of the note which was circulated to Members in July of last year. The investigations described in that note are proceeding but I do not anticipate that they will be concluded in time to enable improvements to be effected during the coming long recess.

Tuberculin tested Herds

Mr KELLY asked the Minister of Agriculture the number of approved tuberculin tested herds in Great Britain.—Mr BERNAYS, Parliamentary Secretary to the Ministry of Health, replied: On March 31st last there were 1795 herds in England and Wales licensed for the production of tuberculin tested milk. I am informed by my right hon. friend the Minister of Agriculture that there are at present in England and Wales 203 attested herds (which are tuberculin tested) on the register kept in his Department. This number includes 84 herds which are also licensed for the production of tuberculin tested milk.

Health of Spanish Refugee Children

Mrs CAZALET asked the Minister of Health what was the present position regarding the health of the Basque children who had been brought into this country.—Mr BERNAYS replied: According to the information in my possession the general health of these children is satisfactory but my right hon. friend is advised that it is highly desirable on grounds of public health that the number of children in the camp at North Stoneham should be reduced as speedily as possible and he understands that the National Joint Committee for Spanish Relief are in accord with this view. Vaccination is in progress, and about 900 of the 4000 children have already been transferred elsewhere. Five cases of typhoid fever, two cases of diphtheria and three cases of measles have occurred among the children. The patients have been isolated and appropriate precautionary measures have been taken against the spread of infection.

Nutrition and Minimum Income

Mr SARGISON asked the Minister of Health whether His Majesty's Government accepted Mr. Seebohm Rowntree's recently published estimate of the minimum income required to provide the essentials of life to which his attention had been drawn; and if not whether his department had made any such estimate of its own.—Mr BERNAYS replied: No Sir. My right hon. friend is advised that this estimate involves certain features that are very conjectural and no sufficient official material for the

preparation of an estimate of this kind is at present available.

Milk Rations for Enlisted Boys

Mr GRAHAM WHITE asked the Secretary of State for War the present amount of the daily milk ration for enlisted boys.—Sir V. WARREN, Financial Secretary to the War Office, replied: The daily ration of milk for enlisted boys is half a pint a day in addition to a variable quantity required for hot beverages, puddings, &c. The boys at the Army Technical School, Bechley, receive three-quarters of a pint a day in addition to one-quarter of a pint for other purposes.

TUESDAY JUNE 8TH

Ex Service Men in Mental Hospitals

Mr KELLY asked the Minister of Pensions the number of ex Service men under treatment in mental hospitals in this country for whose maintenance his department was responsible.—Mr H. RAKESBOTHAM replied: The number of officers, nurses, and other staff for whose treatment in mental institutions my department was responsible at end of May 1937 was 5770.

Scientists Employed by Ministry of Health

Mr MARKHAM asked the Minister of Health how many scientists were at present employed in the Ministry and how this figure compared with that of 1930.—Sir KINGSLEY WOOD replied: On April 1st 1937 the scientific staff of the Ministry other than the medical and dental staffs totalled 13. This figure included a chemist, chemical inspector, alkali inspectors and pharmacists. The corresponding figure at April 1st 1930 was 13. The medical and dental staffs at the same dates were respectively:—

Medical staff	1930	104	1937	115
Dental staff		12		10

In addition the department's establishment in both years included a post of serologist which was temporarily vacant on April 1st last and will shortly be filled.

Vacancies

For further information refer to the advertisement columns.

Abendorn Royal Infirmary—Two Hon. Asst. Ophth. Surgeons
Ashton Hosp.—1—Cas. O., at rate of £150
Ashton Hosp., Kent—Res. M.O. £150
Barnsley Baptist Hosp. and Dispensary—Jun. H.S. £200
Bath Royal United Hosp.—H.P., at rate of £150
Bedford County Hosp.—Second H.S. at rate of £150
Birmingham and Midland Hosp.—H.S., at rate of £130 £150
Birmingham Maternity Hosp.—H.S., at rate of £200
Birmingham Selly Oak Hosp.—Jun. M.O.'s, each at rate of £200
Bolton Royal Infirmary—H.P. and Two H.S.s, at rate of £200 and £150 respectively
Bromford Children's Hosp.—H.P. £150
Brighton Municipal Hosp.—Third Res. Asst. M.O. £300
Bromford Royal Eye and Ear Hosp.—Two H.S.s each £180
Brighton Royal Alexandra Hosp. for Sick Children—H.P. £150
Brighton, Royal Sussex County Hosp.—Cas. H.S. £150
Bristol General Hosp.—Two H.P.s, Three H.S.s, H.S. Obstet. O.H.S. to Spec. Depts each at rate of £250. Also Cas. H.S., at rate of £100
British Red Cross Society Clinic for Rheumatism—Polo-Jr.
Cardiff—King Edward VII Welsh National Memorial Assoc.—Res. Asst. Tuberc. M.O. £300. Also Res. M.O. for South Wales Sanatorium, £250
Carlisle Cumberland Infirmary—H.S. at rate of £155
Central London Broad Way and Lar Hosp. Gray's Inn-road—H.C.—Hon. Asst. to Out-patient Dept.
Charing Cross Hosp.—H.C.—Hon. Orthopaedic Surgeon. Also Hon. Clin. Asst. to X-Ray and Electrotherapeutics Dept.
Chelmsford C.C.—Temporary Tuberc. O. £15 per week
Chesterfield and North Derbyshire Royal Hosp.—Res. Surg. O. £200. Also H.S., at rate of £150
Chichester Royal Naval Victoria Hosp.—Jun. H.S., £125
City of London Mental Hosp. Stone N. Bedford—Asst. M.O. £100
Colegate, Sussex County Hosp.—H.S., £175
Cornwall Hosp.—L.—Hon. Surgeon
Conventry and Warwickshire Hosp.—Res. H.S. and Res. Cas. O. each £150
Down County Mental Hosp. Downpatrick—Jun. Asst. M.O.
Droghda Hosp. Greenwald, S.L.—Res. Living Room Officer at rate of £200. M.O. H.I. and H.C. each at rate of £115

- Durham County Council*—Deputy County M O H, £960 Also Asst Welfare M O, £500
- Durham County Hosp*—H S, at rate of £150
- Dumfries and Galloway Royal Infirmary*—Res H S, at rate of £100
- East Ham Memorial Hosp, Shrewsbury road, E*—Hon Surgeon to Orthopaedic Dept Also two Anaesthetists, each 1 guinea per session

Births, Marriages, and Deaths

BIRTHS

- BATEMAN**—On June 3rd, at Eton avenue, N W, the wife of Mr Geoffrey H Bateman F R C S of a son
- BAYNES**—On June 5th at West Byfleet Surrey, the wife of Dr H Godwin Baynes of a daughter
- CORRY**—On May 20th the wife of Mr Cedric Corry, F.R.C.S., of Oxford, of a son
- KONSTAM**—On June 4th at Wildwood rise, N W, the wife of Dr Geoffrey Konstam of a daughter
- MACLEAN**—On June 3rd, at Devonshire place, W, the wife of Dr D Maclean of Harpenden of a daughter
- MUMFERY**—On June 5th, at Welbeck street W, the wife of Dr Raymond Mumfery, of a daughter
- MURTAGH**—On June 1st the wife of Dr Harold Murtagh, of Ripponden, of twins (a girl and a boy boy stillborn)
- PERCIVAL**—On June 1st, the wife of Lt Col E Percival, D.S.O., R.A.M.C., of Fleet Hants of a son
- SADLER**—On June 3rd at West Witterling Chichester, the wife of Dr O R Sadler, of a daughter
- WAYNE**—On June 4th, the wife of Prof Edward J Wayne F R C P of Sheffield, of a daughter
- WOODHOUSE**—On May 30th at Royal Naval Hospital Portland the wife of Surg Comdr G W Woodhouse of a son

MARRIAGES

- BOYD—PEARL**—On June 3rd at Hungerford Parish Church Douglas Herbert Stuart Boyd, M.B., to Margaret younger daughter of Mr A R Pearl of Hungerford Berks
- LAURENT—BAKER**—On June 3rd at Hampstead Town Hall, Louis Philippe Eugène Laurent M.D. Lond to Phyllis Margaret, only daughter of C H Collins Baker, C.V.O., of the Huntington Library, California
- ROBERTSON—WATT**—On June 3rd, at St Paul's street Congregational Church Aberdeen, Capt. Hamish Gordon Grant Robertson R.A.M.C., to Marjorie Mary Watt eldest daughter of the Lord Provost of Aberdeen
- WARNER—MICHELSON**—On June 4th Frederick Sydney Warner M.R.C.S., L.D.S. to Cecily Florence Michelson

DEATHS

- BARBER**—On June 4th at Haywards Heath Hailford Vaughan Barber M A Camb, L.R.C.P. Lond, aged 83
- BARKER**—On June 2nd at Woking, the residence of his sister in law Percy Duckworth Barker M.R.C.S. Eng aged 63
- BENNETT**—On June 3rd Claude John Fiddows Bennett M.R.C.S. Eng D.P.H. of Inglewood Melksham
- CHUBB**—On May 31st at Pitt street W, William Lindsay Chubb M.B.E. M.D. Durh formerly in practice at Sandgate Kent and Farnborough Hants
- EDGAR**—On June 1st at Trov-court Kensington, W, Peter Galston Edgar M.B. Edin aged 68
- HARVEY**—On June 4th at Letchworth, William Eyer Harvey M.B. Oxon aged 52
- ROBERTSON**—On June 4th at Wellington New Zealand Alexander Robertson M.D. Glasg
- V B**—A fee of 7s 6d is charged for the insertion of Notices of Births Marriages and Deaths

NOTES, COMMENTS, AND ABSTRACTS

PROTAMINE INSULIN

Writing last January Dr P. Wolff¹ of Geneva was already able to review 140 papers on the new insulin compounds with a slow action. The conclusions he draws from these and from his own experience may be summarised as follows:

(1) The treatment of severe diabetes is both safer and simpler with the new compounds than with ordinary insulin.

(2) Absorption being slower wide changes in blood sugar are prevented and hypoglycæmic reactions are less common and milder.

(3) A high fasting blood-sugar is the special indication for protamine insulin since it is of great advantage to the diabetic to begin the day with an approximately normal metabolism.

(4) Insulin-sensitive patients can be more satisfactorily controlled with protamine insulin because frequent reactions are avoided.

(5) Young diabetics respond more favourably to protamine than to ordinary insulin.

(6) The dosage as well as the number of injections can often be reduced by using protamine insulin and some patients are able to abandon insulin altogether after treatment with it.

(7) Diabetics coming under care for the first time should be given protamine insulin for in this way their treatment can be stabilised satisfactorily with a single dose daily.

(8) There are no important disadvantages in the new preparations as compared with the old but in acute cases they are unsuitable and in pre- and post-operative conditions, coma, acidosis and injections they should be only gradually substituted for the old.

(9) Protamine insulin offers a great advance towards giving the diabetic a completely physiological nutrition.

These conclusions sound more favourable to protamine insulin than those contributed to our last issue by Dr Izod Bennett and his colleagues at the Middlesex Hospital. But Dr Wolff is himself doubtful whether any form of retard insulin has yet been sufficiently studied to warrant general use outside the clinic: their administration must be adjusted to individual cases and not applied by any rule of thumb. The possibility that they may offer a better control of the disease as a whole is nevertheless a high one and a more continuously normal level of the blood sugar must be of advantage. E. P. Joslin who has already treated over 700 diabetics with the new preparations speaks of the new Insulogerm and hopes that especially the risk to vessels, nerves and eyes of diabetics may at last be overcome.

HOSPITAL LIBRARIES

MANCHESTER has an advantage over London in the organisation of a hospital library service as hospitals and libraries are both under the control of the same local authority. Mr O. Nowell, chief librarian of Manchester, gave to a meeting included in the annual conference of the Library Association at Scarborough last week an admirable account of what has been accomplished under his direction. Starting with the proposition that a hospital library service is more than the supply of books to patients he described its value to nurses and maids as well as to doctors, engineers, porters and administrative staff. In one hospital belonging to the corporation but many miles from Manchester with a staff of two hundred a collection of books is maintained for their use as well as for the patients and any book specially required by a doctor or other member of the staff can be obtained on request. In London the County Council have an arrangement with the British Red Cross Library which by the terms of

its trust is limited to patients. For the hospitals in Manchester whether council or voluntary there is a special committee working in the closest co-operation with the Corporation Libraries Committee. The organisation is under professional direction with voluntary helpers drawn from a wide range of organisations including the Dickens Fellowship who have been particularly excellent in one hospital. The libraries department is responsible that all books issued are good of their kind in good condition and cared for at least as much as the general library stock. The repair and binding of the books is also supervised by the public library staff. In order to have the assistance of the central committee it is essential for a hospital to have a recognised supervisor in charge belonging preferably to an already existing organisation created for some wider purpose which gives strength to the team and provides the very necessary reserves for substitutes. Members of the League of Women Helpers have been particularly acceptable on this account.

The qualifications of the library helper were described by Mr Nowell to be 'A book lover but no highbrow, a pleasing personality with not too much of the bedside manner, the capacity for not just taking on a job of work but for sticking to it; loyalty to the service and a love of it for its own sake. The principal difficulty has been to find suitable rooms for library purposes and Mr Nowell entered a plea that for all new hospitals a library department—centrally situated—will be planned. Special reference was made to mental hospitals and Mr Nowell expressed his conviction that this work to be successful must be in the hands of a trained librarian; though at the same time he did not regard the service as highly specialised but rather that the patients should be catered for exactly in the same way as the general reader in the public library.

It is clear that under professional direction the work of voluntary helpers can be rendered more efficient and the service more beneficial to the patients and staff whether in general or mental hospitals.

THE BIOCHEMISTRY OF MILK SECRETION

ON May 1st we referred to the intensive study of milk production now being made at the National Institute for Research in Dairying at Reading—a study which must stimulate analogous thought on human lactation. In a paper since read before the Royal Society of Arts, Prof. H. D. Kay, now director of the Institute, described the influence on lactation of various factors including hormones. The parts played by hormones in bringing about mammary development and lactation long suspected are now sufficiently understood for the processes to be induced in the male of some animals by means of oestrin, progesterin and prolactin; but the effects of hormones of oestrin and thyroxine in particular on established lactation in the cow are not what would be immediately guessed from clinical experience. If a sufficient dose of oestrin is administered to a lactating cow the animal is brought into season within a few hours and there is also a moderate fall in the milk volume. This accords with most farmers' experience that the quantity of milk often falls when a cow comes into season. But the fall caused by oestrin is succeeded by a rise to the previous level or even above and at the same time an increase of the order of 10 per cent. in the proportion of fat and non fatty solids in the milk. The increase if the dose of oestrin is large may persist for considerable periods having been observed in two cows for two months. Perhaps the minor digestive disturbances that commonly affect infants when their mothers menstruate during lactation may be attributable to an enrichment of the milk comparable to the enrichment seen in these cows.

Thyroxine and dried thyroid were dramatic in their effect on cows the milk yield increasing by 20-30 per

¹ Über klinische neue Arzneimittel. II. 5. Insulinpräparate mit verzögerter Wirkung. H. Wolff. Bericht d. Intern. Kongresses med. Jahrbuch. Basel. H. Schwabe and Co. 1933.

cent, the fat by 16 per cent, and the total yield of butter fat per day by 50 per cent. If a similar effect is obtained in women it will seem that the anxiety of some types of mother, which is traditionally a cause of failure to breast-feed, is not related to excessive thyroid secretion.

Speaking of the excretion of individual constituents of milk Prof Kay said that the amount of phosphatase in milk may be taken as an index of the efficiency of the gland, its concentration is least in the milk at the height of normal lactation and is also low in the abundant and rich secretion of milk after thyroid administration. In mastitis, on the other hand, the phosphatase concentration is high.

Comparison of the venous and arterial blood of the gland has shown that in all probability the lactose of milk is derived from blood glucose, the several phosphorus compounds from the inorganic phosphate of the plasma (and not from the much larger quantities of organic phosphorus compounds in the blood), and part of the casein and the albumin from circulating amino-acids.

NUTRITIONAL RETROBULBAR NEURITIS—Dr Fitzgerald Moore asks us to say that in his paper published in our issue of May 22nd a sentence on p 1226 under the heading of Aetiology should read "Thus it has not been possible yet for me to prove therapeutically that ophthalmological response is due to vitamin-B, treatment exclusively, but other general evidence is so strong that I believe this certainly to be only awaiting confirmation in this respect." In the article as printed the word italicized appeared as *vitamin-B*.

ADDRESSES AND ORIGINAL ARTICLES

CHANGE IN THE AGE OF MORTALITY FROM DIPHTHERIA

By R. M. F. PICKEN M.B. B.Sc. D.P.H.

MANUEL TALBOT PROFESSOR OF PREVENTIVE MEDICINE, WELSH NATIONAL SCHOOL OF MEDICINE

THIRTY years ago Murphy (1907) drew attention to variations in the age of mortality in London from certain diseases, including diphtheria. His charts will still repay study. For diphtheria he showed that in the years of high prevalence from 1861 to 1885 the mortality at ages 4-5-10 and 10-15 was low as compared with the average rates at these ages over the whole period 1850-1905 that the relative immunity at these ages gradually disappeared as the years progressed and that when high prevalence occurred in 1896-1900 it had been replaced by excessive susceptibility in relation to the average over the whole period. At younger ages the reverse had occurred. Briefly diphtheria appeared to be attacking and killing children of school age to an increasing extent. He saw evidence of a waning of this movement with falling prevalence in 1901-05 and said of the increasing part taken by older children up to the end of the nineteenth century "I think this may probably be a natural increase, although it may have been accentuated by increase in aggregation of children at school. However this may be, I should expect to find the first evidence of recurrence of epidemic prevalence of diphtheria in increase of relative incidence upon ages 4-5-10 and 10-15." He hoped that the figures for subsequent years would help to determine whether these changes were rhythmic.

Since Murphy wrote the question has received a good deal of attention. Chalmers (1913) described a similar fallure of the mortality at ages 6-10 to decline at the same speed as at younger ages in the death statistics of Scotland for groups of years from 1860-62 to 1908-11 and identified a progressive transference of notifications in Glasgow from ages under 5 to ages 6-10 during the years 1903 to 1912. Collis (1925) comparing the specific death rates in England and Wales for 1901-10 with those for 1861-70 demonstrated a decline at all ages over 10 but an increase in both sexes at ages 0-5 and 5-10 the latter being the greater. Woods (1928) expressed these specific death rates for England and Wales as percentages of the standardised death rates from diphtheria for decennia from 1861 to 1910 and for the four year period 1921-24 and showed conclusively that fatal diphtheria in 1921-24 as compared with 1861-70 and 1871-80 was concentrating on the age group 6-10 while remaining stationary or tending to decline at younger and older ages.

In a very full discussion of the mortality from diphtheria in England and Wales and in London Forbes (1932) brought the records up to 1929 and traced from period to period since 1871 the changes of mortality in five year age-groups up to 20-25 years. He tentatively confirmed Murphy's observation that diphtheria tended to become relatively more fatal in the later age groups during times of high prevalence especially in London. He suggested further that there was evidence that this process was extending even to young adult ages in recent years. The Registrar General (1934) in an illuminating table compares the rates of mortality at single ages up to

5 and at ages 10-15 with those at ages 5-10 for individual years 1901-34. He shows that throughout the whole of this century there has been a progressive shifting of mortality risks toward school age and mentions a similar change in Prussia. His table indicates that the risk at ages 10-15 in post-war years had been on the whole greater than pre-war even when expressed in terms of the rapidly rising risk at ages 5-10.

MORTALITY AFFECTED BOTH BY INCIDENCE AND BY FATALITY

With the exception of Chalmers these writers have each confined their attention to mortality, reasonably assuming that age-mortality was a measure of age-prevalence. Chalmers's table of notifications in Glasgow expressed the cases in each age-group as a percentage of the total at all ages in each year taking no account of changes of age of the population. The transference of notifications to school age appeared to be taking place too rapidly to be explained entirely by such changes. It has seemed to me that the respective factors of incidence and fatality might be worthy of further exploration. The most satisfactory way of doing so would possibly have been to investigate the age-fatality of hospital cases, but unfortunately it is impossible to get such statistics of sufficient magnitude in satisfactory age groups over a long series of years without putting others to labour which hardly seems justifiable. Woods (1933) discusses at some length the value of notification records and of hospital fatality rates, and concludes that they both have their defects. She points to the obvious fallacy arising from increased bacteriological diagnosis of diphtheria in recent years swelling the toll of mild cases. Indeed this, among other problems, has caused the London County Council to issue a special report on the nomenclature of diphtheria (1936) and to include the special designation bacteriological diphtheria in its tables of hospital discharges. Nevertheless the graph of notification rates in England and Wales for diphtheria and scarlet fever (which tend to run in harness) shows little divergence throughout the period since 1911 for which these figures are available, suggesting that bacteriological methods have not greatly increased the number of notifications in recent years throughout the whole country. It is not possible to determine whether other changes of fashion have raised the notification rates for both diseases. In London however with which this paper is largely concerned there does seem to have been an exceptionally high notification rate for diphtheria since 1921 a fact upon which the Registrar General has commented from time to time. A part therefore of the apparently great fall in fatality in recent years is probably artificial and the fact that it is demonstrable in hospital statistics does not detract from this conclusion since very few notified cases nowadays fail to be admitted. The picture is still further confused by the exceptionally large proportion of wrong or doubtful diagnoses of diphtheria. The important question for practical purposes is whether these fallacies may be differential as regards age-groups. As a test of the validity of placing certified deaths against notifications rates have been calculated and compared with hospital fatality rates so far as these are available as shown in Table A.

The age-distributions of the fatality of all cases and of hospital cases were somewhat different in the first ten years of the century. In this connexion it may

be noted that the proportion of hospital admissions to notifications was only 65 per cent in 1901-05 and 67 per cent in 1906-10, whereas in 1935 it was 99 per cent (if all the cases admitted and classed as "bacteriological diphtheria" were included among the notified, even if they were all excluded the

TABLE A—London Diphtheria Fatality at Certain Ages as Percentage of Rate at 5-10 Years (Rates based on all Notifications and Deaths compared with Hospital Rates)

Period	—	0-5	5-10	10-15
1901-05	{ All cases Hospital cases	224 188	100 100	36 42
1906-10	{ All cases Hospital cases	240 191	100 100	28 53
1932-35	All cases	125	100	49
1935	Hospital cases	131	100	39

percentage of admissions was 88). In the earlier years, then, it is likely that the fatality at ages over 5 was weighted in hospital by the admission of a preponderance of grave cases, and it is also possible that a large proportion of the rapidly fatal cases under 5 used to die at home. However this may be, the indices are reasonably similar in magnitude and trend, it seems that no very great fallacy will arise from studying specific fatality rates based on notifications and deaths.

SOURCES OF INFORMATION

In pursuing an investigation of this kind one has to take data where they can be found. Notifications for England and Wales are available only since 1911 and they are not classified by age and sex. The material has therefore been derived from London, Manchester, and Glasgow. At the outset it should be said that what has happened in these large towns is not necessarily true for other parts of the country. There is some evidence that it is not. Unfortunately most of the annual reports of medical officers of health group together the notifications and deaths from infectious diseases at all ages from 5 to 15, and the Registrar General classifies local deaths in the same way. For the diseases predominantly affecting childhood such classification is of little value, and it is therefore difficult to carry the inquiry into many areas.

AGE MORTALITY IN ENGLAND AND WALES

In order to test whether the movement of specific death rates in London is comparable with that in England and Wales rates have first been calculated for the whole country. These differ from the figures given in the papers quoted above, as they apply to groups of five years around censuses commencing in 1901. Earlier data have not been used because comparisons between the records of diphtheria of last century and the present are questionable. In the early days of registration scarlet fever was imperfectly differentiated from diphtheria and croup was only diphtheria to an undetermined extent, although it has been customary to combine the two causes. Moreover, notification, with its stimulus to diagnosis, became universal only in the last decade of the nineteenth century and almost immediately thereafter antitoxin treatment began to affect mortality. In spite of the increasing influence of bacteriological diagnosis the figures of the past 37 years have probably a more uniform meaning than formerly. In all the tables in this paper deaths

* In this and the other main tables, rates in age and sex groups over 15 years have been omitted. They have been calculated, but the numbers of cases and deaths are too small to give rates of significance. The actual numbers of cases and deaths in the three age groups of childhood are included in some tables because they are not very easily found elsewhere.

† In Tables I, II, and III this is based on census populations of the central year in each period.

D R.—Mean annual death rate.

from croup—which are very small in number—are ignored.

Table I bears out the general observation that diphtheria has greatly declined in England and Wales as a cause of mortality at all ages under 15 years, and that there has been little difference in this respect as between the sexes. Males, however, as has been frequently noted, have succumbed to a greater extent at ages under 5 the reverse being markedly the case at ages 5-10 and 10-15, so that the

death rate among females at the combined ages 15 consistently higher. The relations between the specific rates may be expressed as in Table B.

When the death rate at ages 5-10 is represented as 100 for males or females or both sexes the index for children below these ages is seen to have fallen from about 200 to a figure approximating to 100. For females the two rates have become identical.

At ages 10-15 mortality is increasing in importance even as compared with the rate at 5-10 years and therefore much more in relation to the rate under 5 years. Death is sparing the very young far more than those of later ages.

SPECIFIC RATES OF MORTALITY INCIDENCE AND FATALITY IN LONDON

In Table II corresponding rates are given for London. The deaths for 1931 are not available in the required age-grouping and those for the sexes separately cannot easily be obtained for any of the last group of years. The relations of the specific rates may be summarised as before in Table C.

TABLE C—London Diphtheria Mortality at Certain Ages as Percentage of Rate at 5-10 Years

In London the movement has been the same as in England and Wales although children under 5 years have been, and continue to be relatively more affected than in the country generally. So far as the comparison extends the mortality under 5 years has again

exceeded that at ages 5-10 to a greater extent among males than females.

Whether this movement and these relations are attached to incidence or fatality remains to be examined. Using notifications as a measure of

incidence I have prepared Table III for the periods covered by Table II. It shows the specific case rates. Their relations are exhibited, as before in Table D.

Selective incidence among males under 5 years seems to follow their selective mortality and indeed, as will be shown later may be the main explanation of it. The notification rates for the combined sexes at ages under 5 and at 5-10 have not been very different from one another in each period. Such decline as has occurred in the relative importance of the younger ages is moderate and uncertain and has not been carried on to the most recent period.

TABLE D—London Diphtheria Incidence at Certain Ages as Percentage of Rate at 5-10 Years

Period.	0-5			5-10		10-15	
	P	M	F	—	P	M	F
1899-1903	104	118	93	100	37	36	23
1909-13	8	111	85	100	37	35	34

1919-20, 21, 22, 23	95	—	—	100	35	—	—

When the case rates in the age-group 0-5 are compared with the corresponding rates at ages 5-10 practically all the differences lie within errors of random sampling. The tendency of the mortality at later ages to assume increasing importance may have

been partly due to a shift of incidence, but this explanation does not apply to the most recent years when this shift has been less pronounced than in the two preceding periods. It may be noted that the first and third of the four periods included

years of exceptionally high prevalence, but they are least in accord as regards the relative incidence at early and later ages.

In Table IV the proportions of deaths to notifications in age and sex groups in London are shown for the same periods of years as before. Diphtheria has tended to be less fatal among all female children than males, but if there is any real difference it is due to the relative exemption of females from attack at ages under 5, for the fatality at this age and at ages 5-10 is, if anything, greater. Over the periods under review the proportion of deaths to notifications has fallen greatly. So probably has the real fatality, although it would be difficult to determine the influence of increased bacteriological diagnosis on these rates. If diagnosis were assumed to have been more thorough

TABLE E—London Diphtheria Fatality at Certain Ages as Percentage of Rate at 5-10 Years

in 1919-23 than in 1909-13 then diphtheria must have been definitely more virulent in the later period, for the fatality, even as here measured, was slightly greater in each of the three five year age groups under 15 years. The relations between the rates at different ages throughout this series of years may be expressed, as before, in Table E.

The post-war shift of mortality to later ages is seen to have been accompanied by a very similar change in the fatality relations. In this case the figures, so far as they go, indicate that the change of fatality from the disease has not been different as

C = cases D = deaths F = fatality

between males and females. When read in conjunction with the movement of incidence rates, the above table indicates that in the last period the movement of mortality to later ages is entirely due to the increasing importance of the fatality at these ages.

The comparison is carried further in Table V which covers two almost continuous series of years from 1901-10 and from 1921-35. The most impressive features of the table are the fall of fatality at ages under 5 years, and the recent arrest of the decline at later ages. This is especially striking in the last four years when a rise at ages 5-10 and 10-15 has been sufficient to increase the rate at all ages under 15, although that at ages under 5 years has continued to fall slightly. These points are epitomised in Table F.

As there is no pronounced or uniform difference in the sexes, it is perhaps of little importance that

the rates for males and females separately are not available for 1932-36. Although fatality at ages 5-10 has been relatively more important during the whole post-war period the movement has fluctuated. The figures on which the rates are based are

TABLE F—London Diphtheria Fatality at Certain Ages as Percentage of Rate at 5-10 Years

Period	0-5			5-10	10-15

For the sexes separately the period is 1926-29

ably large and the irregularities are probably real. It can readily be understood that variations in the social classes affected by the disease from time to time might heavily influence the fatality at older

London Diphtheria fatality at certain ages as percentage of rate at ages 5-10

of the medical officer of health of Manchester has included tables of the cases and deaths of each of the important infectious diseases in short age-groups (sexes undistinguished) since 1891. In his report for 1933 Dr Veitch Clark commented upon the change of age incidence of diphtheria in the last twenty years. Table VI presents an analysis of the figures of cases and deaths since the beginning of the present century excluding the decade in which the war occurred. The proportion of deaths to notifications at all ages under 15 years has usually been more than twice as high as in London.

It is difficult to believe that this great excess can have been entirely due to less observance of notification in a large town which has a vigorous health department, and is also a teaching centre in medicine

1931-35	937 139 13.79 ± 1.11	1717 174 10.13 ± 0.73	764 41 3.37 ± 0.61	3438 317 10.09 ± 0.60

Part of it may be due to deliberate exclusion of unverified cases. This however is not the main point at issue. The relative importance of the fatality at ages may be tested, as before in Table G.

The movement is not quite the same as in London. The smaller numbers for Manchester make the comparison less valid. By chance the relationships in any one of the quinquennia might have been very different but it is probably more than a mere

TABLE G—Manchester Diphtheria Fatality at Certain Ages as Percentage of Rate at 5-10 Years

Period	0-5	5-10	10-15
1901-05	166	100	3*
1906-10	221	100	36
1921-25	233	100	67
1926-30	210	100	36
1931-35	136	100	3

coincidence that here also the fatality at ages 5-10 has become more important in the last ten and especially the last five years. Indeed, when the specific rates of deaths to notifications over the whole series of years from 1891 to 1930 are calculated * and compared with the rates in 1931-35 they show a significantly different relationship between the rates for the two lower age groups from that which holds at the present time.

FATALITY RATES IN GLASGOW

From records given by Chalmers (1913) and others contained in the annual reports of the medical officer of health of Glasgow specific proportions of deaths to notifications can be calculated for certain years and these are set out in Table VII. Expressed as before the fatality rates are related as in Table II.

The proportions of deaths to notifications at all ages under 15 years have been comparable with those in London but much lower than in Manchester although the social circumstances and medical standards of the two industrial cities are not dissimilar.

Ages 0-5: 2715 cases, 2463 deaths, fatality 90.7 per cent
Ages 5-10: 870 cases, 1014 deaths, fatality 117 per cent
Ages 10-15: 294 cases, 137 deaths, fatality 46.6 per cent

	D	358	175	41	574
	F	10 44 $\pm$ 0 51	3 88 $\pm$ 0 29	2 46 $\pm$ 0 38	5 08 $\pm$ 0 24
1934-35	C	1 377	1,979	876	4 232
	D	147	93	18	258
	F	10 67 $\pm$ 0 83	4 70 $\pm$ 0 48	2 05 $\pm$ 0 48	6 10 $\pm$ 0 37

Since 1924 the fatality at these combined ages seems to have fallen little, if at all, and at ages 5-10 the tendency has been upward although the numbers are too small to establish the movement definitely. Here, again, it may be said that the relative importance

TABLE H—Glasgow Diphtheria Fatality at Certain Ages as Percentage of Rate at 5-10 Years

Period	0-5	5-10	10-15
1903-07	270	100	47
1908-12	282	100	50
1924-28	335	100	22
1929-33	269	100	63
1934-35	227	100	44

of the fatality at ages has varied from time to time, but that there is the same recent tendency for the ages 5-10 to count more heavily, especially in the last two years

DISCUSSION

The fall in the death rate from diphtheria throughout the present century has been great and fairly continuous in England and Wales. As would be expected local fluctuations are more pronounced, but the trend is downward. Like scarlet fever the disease is generally thought to be no less common than formerly, and notifications, for what they are worth, and especially in their contemporaneous fluctuation with those of scarlet fever, support this view. If it is correct, diphtheria is following scarlet fever in becoming a less fatal disease, and this amelioration may not be entirely due to better, earlier, and more frequent treatment in hospital. If it is, as in the case of scarlet fever, a process not dependent upon ad hoc measures, other changes in the behaviour of the two diseases might be expected to agree. Woods (1928) has shown that diphtheria mortality has reacted less at ages 5-10 than at other ages, although the general tendency of death to be transferred to still later ages observed in scarlet fever was not demonstrable for diphtheria over the period with which she dealt. The Registrar-General (1934) does, however indicate that this movement is extending into ages 10-15. The specific death-rates shown in this paper for England and Wales and for London confirm this tendency. There is, therefore, some ground for believing that a process common to the two diseases is at work.

The assumption that these changes in the specific rates of mortality are due to changes of incidence seems to be only partly justified. Incidence rates, and the proportions of deaths to notifications at ages in London indicate that the state of affairs is more complex. On the whole there may have been a relative reduction in the case rate at ages under 5 years, as compared with later ages, until recently but it is not specially notable in the quinquennial period around the census of 1931. On the other hand, since the beginning of the century the decline of the fatality under 5 years of age in London has been much more rapid than at later ages. This also has not been a perfectly continuous movement, but it is revealed to a most striking extent in the rates for 1932-35 in comparison with earlier years and especially with the first decade of the century. In Manchester the fatality under 5 years has figured much less prominently in 1931-35 than in any other post war period or in the quinquennium 1906-10, but an exceptionally high fatality at ages 5-10 in 1901-05 served to reduce the relative importance of the younger ages. The movement is somewhat similar in Glasgow over the period for which data are available, but it may have set in later and it certainly has not gone so far as in London or Manchester. In all three cities the most prominent factor in the recent increase, or arrest in the decline, of fatality at all ages under 15 years has been a rise in the fatality at ages 5-10, although the small changes in Glasgow are equivocal.

It seems unlikely that this shift of the fatality is artificial. The educational period of life is that at which detection is likely to be most complete and notifications, indeed, to be inflated, so that the apparent fatality at ages 5-15 should have fallen most since the inception of the school medical service. Again, it is probable that immunisation in London and Manchester (it has not been extensively practised in Glasgow) has reached a higher proportion of school than of pre-school children. A table contained in the annual report of the medical officer of health of Manchester for 1935 indicates that this is especially true of the age group 5-10 in that city. As protection is a matter of degree it might have been expected to lead to an increase in the proportion of less fatal cases of diphtheria at these ages, and so to reduce the average fatality rate at the period of life when the reverse appears to have happened. Incidentally, the suspicion expressed by Dudley and others (1934) that immunisation, by creating carriers, would increase the risk for pre-school children is not so far confirmed by the incidence or mortality in London or Manchester.

The theory tentatively mentioned by Murphy and quoted by other writers, that the relative hesitancy of the mortality at ages 5-10 to fall at the end of the nineteenth and the beginning of the present century was due to aggregation of children in school, will hardly bear examination. It has been continuous over a long period without any increase in the aggregation, and it has apparently not been mainly a change of incidence. The excess incidence on females as compared with males at ages 5-15 hardly seems to lend itself to the explanation that they are brought more into contact with younger infective children.

It is interesting, but perhaps not very profitable, to speculate on the natural processes that might account for the movement. Such differences are not peculiar to diphtheria. They can be seen in the comparison between epidemics of any infectious

disease affecting urban and rural communities notably those which like poliomyelitis are sporadic over long periods but occasionally take on epidemicity (Friedemann 1928 and Aycock 1928). The age-variation of Schick immunity by class and locality is now a matter of common observation and is associated with differences of age mortality. The relative infrequency of patent or latent infections in a community might allow its herd immunity to decline (Dudley 1936) so leading to a change in the relative susceptibility of the population at later ages to contract the disease and die of it. Considerable periods of low prevalence of diphtheria do occur in localities and it would be interesting to compare the age-incidence and age-fatality of the disease during the months of rise and the period of decline in the aggregate of a series of epidemics, if numbers of sufficient magnitude could be observed. So far as the data in this paper go they do not indicate that exacerbations of incidence are the governing factor although the point may have been obscured by the periods chosen for analysis.

The most striking instance of unusual age mortality of a disease in modern times was afforded by the influenza epidemic of 1918-19. It seems to have been due less to departure from the usual age incidence of the disease than to a change in the ages affected by its chief mortal complication (pneumonia) accompanied by a change in the age-fatality of that complication (Collins 1931 1934). No explanation but an alteration in the nature of the virus or its symbiotics seems to meet this case. In connexion with diphtheria the most notable observation in modern times has been the differentiation of the corynebacterium into types. In a summary of the position Cooper and others (1936) comment on the fact that a change of predominance from intermediate to gravis strains occurred in Manchester between 1933 and 1934, but less detailed information is available as to the position in London and Glasgow. In neither of these towns does there seem to have been an excess of gravis strains at any time when examinations were made during the years 1933 to 1935 but the proportion of mitis strains was low in London. The association of mitis strains with laryngeal diphtheria is now generally recognised (Cooper and others 1936). A reduction in the prevalence of these strains might therefore be attended by a fall in the fatality among very young children who succumb most readily to laryngeal involvement while a rise of the more toxic gravis or intermediate strains might increase the risk for those a little older. I understand that such a reduction of laryngeal diphtheria in recent times has been noted in London.

PRACTICAL CONSIDERATIONS

The present policy of health departments is to concentrate on the immunisation of children in the second year of life. This is no doubt sound in theory as a means of gradually building up an immune population. The argument often used however in support of the practice—viz. that diphtheria is especially fatal under 5 years—is less valid at the present time than it used to be. It is easier to persuade parents to accept immunisation for school children and much easier to organise its administration at these ages. In view of the increased part taken by the age group 5-10 and to some extent 10-15 in mortality there is much to be said at the present time for adhering to the earlier policy of making sure that the younger school population is thoroughly dealt with while using every possible

means of persuasion to induce parents to accept immunisation also for infants at the end of the first year of life.

SUMMARY

1 The well known shift of diphtheria mortality from pre-school to school ages in England and Wales and in London is shown to have been continued up to recent times.

2 In London it is apparently not due entirely or even mainly to a change of incidence.

3 There has been a shift of fatality to later ages in London which is most striking in the period 1932-35. It is probably not artificial.

4 A similar change in fatality can be traced in Manchester and Glasgow but should not be assumed to have occurred in other areas.

5 The explanation may possibly be found in changes of strain of *Corynebacterium diphtheriae*.

6 It is suggested that immunisation of the younger school-children should not be neglected in favour of infants at the end of the first year of life.

I am indebted for some of the records used in this paper to Dr W. Gunn, medical superintendent to the North Western Hospital, London, to Dr R. Veitch Clark, medical officer of health, Manchester, and to Dr A. B. Macgregor, medical officer of health, Glasgow, and for making extracts from many reports for me and advice on certain statistical points to Mr W. T. Russell of the London School of Hygiene and Tropical Medicine. None of them is responsible for the way in which the figures have been used.

MASSIVE SPONTANEOUS INTRAPERITONEAL HÆMORRHAGE (SPONTANEOUS HÆMOPERITONEUM)

By JOHN BRUCE, M.B. F.R.C.S. F.D.M.

LECTURER IN CLINICAL SURGERY AT THE ROYAL INFIRMARY
EDINBURGH

(From the Department of Clinical Surgery, University
of Edinburgh)

MASSIVE intraperitoneal hæmorrhage is occasionally encountered as a sequel to traumatic malignant disease and in the female ectopic gestation. Apart from such circumstances, spontaneous bleeding of serious degree is one of the rarest of vascular accidents and certainly one of the rarest of acute abdominal catastrophes. In individual experience it is so infrequent that when it is discovered at operation for acute abdominal symptoms the surgeon is apt to be embarrassed and inadequate both in his investigation and in his treatment.

The cases presented here have certain features of interest which make them worthy of report, and I have thought it well to review what has been written on the subject, in an endeavour to determine what exploratory procedures are likely to be useful on such occasions.

SPONTANEOUS INTRAPERITONEAL HÆMORRHAGE IN THE FEMALE

CASE 1—The patient, a well-developed girl of 19, was admitted to hospital with a history that on the previous day she was seized with spasmodic pain in the lower abdomen. The pain was worse on the right side, and she thought that at the beginning it radiated to the back. On the day of admission she vomited on two occasions. There were no urinary or bowel symptoms of note, and the menstrual history was normal. She was, however, due to menstruate on the day of admission.

On first examination the clinical findings were largely negative save for some deep tenderness in the right iliac fossa. A tentative diagnosis of mild catarrhal appendicitis was made, and it was decided to admit her for observation. In the course of the forenoon, however, her temperature, previously normal, rose a little, the pain in the lower abdomen increased, and some lower abdominal rigidity appeared. The diagnosis was apparently confirmed and operation was advised. By the time it was carried out her condition had become further aggravated. The pulse was rapid, thready and her complexion was greivish, her facies anxious, and she was very restless.

The abdomen was opened by McBurney's method, and at once there was an escape of bright red fluid blood containing some clots. The appendix and cæcum were normal, and accordingly a paramedian incision was now made and the pelvis inspected. It contained a large quantity of blood, and after this was evacuated the source of the hæmorrhage was found to be a ruptured cyst in the left ovary, which even then was bleeding very profusely. The remainder of the ovary, the tubes, and the uterus were all congested, probably because she was due to menstruate. A left oophorectomy was carried out and the wound closed without drainage. The recovery was completely uneventful.

I had on several occasions operated on cases of ruptured ovarian cysts in which there was a small amount of blood in the pelvis. Indeed, along with ruptured ectopic pregnancy, this condition constitutes the bulk of intraperitoneal bleedings in the female sex. Seldom, however, does the hæmorrhage attain the massive proportions which it did in this instance, and it is rarely sufficient to be a source of danger. Phaneuf (1924) has recorded 42 examples of the condition and finds there is fairly equal liability to the accident in the follicular and the luteal varieties of cyst. A rarer and less well recognised cause of hæmorrhage in the female is rupture of the dilated or varicose veins which are occasionally found on the surface of a subperitoneal fibromyoma of the uterus. Ernst and Gammeltoft (1921) reported 23 cases of this kind, and pointed out that the accident is apt to be fatal if the rupture takes place into the broad ligament.

Spontaneous hæmoperitoneum from rupture of an ectopic gestation has a more serious prognosis than the other varieties, for the blood remains sterile only for a few hours. Thus, of 17 cases recorded by Dudgeon and Sargent (1905) in only 7 was there no infection after two hours. The usual infecting organism was the *Staphylococcus albus*, and it is to infection that the febrile course of the condition is apparently due.

It is abundantly obvious that in the female the source of intraperitoneal hæmorrhage is usually to be looked for in relation to the pelvic viscera. Nevertheless there are instances in which the bleeding

originates in conditions common to both sexes, and these will now be considered.

SPONTANEOUS HÆMORRHAGE COMMON TO BOTH SEXES

A variety of conditions that are common to the two sexes may manifest their presence by severe intra abdominal hæmorrhage, and their nature is often obvious at operation. This is true of spontaneous ruptures of the spleen (Bailey 1929-30), and liver (Bruce 1929), rupture of the splenic vessels in cirrhosis of the liver (Pyrah and others 1929, Ogilvie 1922), oozing from the liver in toxic hepatitis (Peck 1905), and in undulant fever (Box and Bamforth 1925), and ruptured mycotic aneurysm in acute bacterial endocarditis (Wilhus 1935).

Besides these, two types of spontaneous hæmorrhage are of especial interest. In the first, the bleeding occurs from an arterio sclerotic vessel, and the condition is generally and appropriately known as abdominal apoplexy. In the second, the source of the hæmorrhage and the underlying cause have not been discoverable at operation. It is on this latter type, especially, that the following cases are thought to have a bearing.

CASE 2—The patient was an unemployed man 34 years old of muscular build. For two days he had suffered from indefinite abdominal pain, and, six hours before admission, while standing at the doorway of the "close" in which he lived, he was seized with violent epigastric pain and with pain in the left shoulder. Both persisted in acute form. Nausea was experienced shortly after the pain began and he vomited within the hour. There were no other significant features in the history, but he did admit to suffering from chronic indigestion for an unspecified number of years.

When I examined him he was very restless and looked ill. He presented a curious plethoric or cyanotic appearance, and was very thirsty. The temperature was sub normal, the pulse rate, to begin with, only 76. The tongue was dry and slightly furred. The abdomen appeared to be distended, and the respiratory excursion was limited. Palpation disclosed fairly generalised tenderness, and muscular rigidity was present in the epigastric area. The liver dullness was of normal extent, elsewhere percussion gave a rather dull note over the major part of the abdomen, and especially in the flanks. The other systems were not abnormal in any obvious way.

The diagnosis was somewhat in doubt, but was thought to lie between an acute pancreatitis—which was favoured by his rather cyanotic colour—and a leaking gastric ulcer, the abdominal rigidity, the shoulder pain, and the former history of digestive trouble seeming to support the latter. Operation was advised and carried out within an hour of admission, by which time the pulse rate had risen considerably. The abdomen was opened by a right paramedian incision, and immediately the peritoneum was incised there was a gush of bright red fluid blood. A very large quantity of blood was thereafter evacuated, along with some large clots, and it was some time before the viscera could be adequately inspected. The stomach, duodenum, and pancreas were all normal. There was no rupture of the liver or spleen and no definite bleeding point could be identified. The condition of the omentum and the mesocolon was noted at the time. Each contained several small discrete hæmatomata and appeared somewhat congested. The pelvis was investigated after the incision had been enlarged, again with negative results. Accordingly, a small rubber dam was left in situ and the wound closed.

In the days succeeding operation an attempt was made to identify the presence of any blood dyscrasia, but the Wassermann test was negative, the blood counts within the limits of normality, and the differential blood count normal. The coagulation time and the platelet count also gave the usual readings. His progress was interesting. For the first six days vomiting was frequent he could retain nothing by mouth. After that he improved markedly, the vomiting stopped and he had a very

good appetite. In two weeks there was an intermittent pyrexia, due probably to the absorption of the intra-peritoneal blood; thereafter the temperature settled and his further recovery was uneventful. Seen at intervals since he has remained well and has had no further abdominal trouble of any kind.

I have been able to trace only one exactly comparable case, previously reported in this journal by Hartley and MacKeechie (1934).

His patient was a labourer aged 31 who experienced on rising in the morning a sharp pain in the left upper abdomen which was relieved by vomiting. Some hours later the pain recurred and he was admitted to hospital where his condition became so rapidly worse that laparotomy was decided upon. The operation findings are of great interest: there was a considerable quantity of blood in the peritoneal cavity and the omentum showed a series of discrete hæmatomata in its substance. The patient did not survive many hours and autopsy confirmed the operative findings in that no definite source of the hæmorrhage could be found.

Hartley and MacKeechie suggested somewhat provocatively that the condition be called *splanchnostaxis*.

A case of Churchman's (1911) though not exactly comparable, has certain points of similarity.

His patient was a man of 48 who for some years had suffered from constipation with dull abdominal pain and who finally came under his care with acute abdominal symptoms suggesting acute appendicitis. Shifting dullness was present in the flanks, and it was accordingly assumed that peritonitis had supervened. Operation revealed only intraperitoneal hæmorrhage and the patient died in three hours. At autopsy there was a hæmatoma in the rectal wall, and some ecchymosis in the neighbourhood of the pylorus and at other points in the small intestine. The bowel wall on section showed dilatation of the subserous vessels and intramural hæmorrhage.

Churchman regarded these findings as in keeping with hæmophilus largely because intraperitoneal and intraperitoneal hæmorrhages are known to occur in fatal cases of this disease and in experimentally produced hæmorrhagic disease (Whipple and Sperry 1909). This suggestion has not altogether been accepted and indeed Osler and McCrae (1926) regard Churchman's case as an acute form of hæmorrhagic peritonitis of which disease they also recognise a chronic variety analogous to the hæmorrhagic pachymeningitis described by Virchow. The chronic form is localised most commonly to the pelvis and its pathological manifestations take the form of the deposit on the surface of the peritoneum of successive layers of young connective tissue containing numerous large wide vessels from which repeated hæmorrhages take place.

In my own case and in the case of Hartley and MacKeechie the possibility of a hæmophilus or a hæmorrhagic peritonitis cause was quite definitely excluded and in view of the complete recovery on the one hand and the absence of demonstrable visceral or peritoneal post-mortem pathology on the other it is necessary to fall back on a vascular disturbance to explain the bleeding.

Spontaneous hæmorrhage from an arterio-sclerotic vessel is always a possibility in the abdomen as elsewhere. Nevertheless considering the great frequency of arterio-sclerotic vascular degeneration and the fairly common occurrence of gross visceral aneurysm the spontaneous rupture of visceral and peripheral arteries is remarkably rare. The accident indeed has been reported only on six occasions—

Hillard (1918)—Male aged 48. Sudden onset of abdominal pain with rigidity. Laparotomy showed

hæmorrhage but definite bleeding point not found. General arterio-sclerosis.

Starck (1923)—Spontaneous rupture of the gastroduodenal artery in a male aged 60 with arterio-sclerosis. Green and Powers (1931)—Sudden epigastric pain with rigidity after spontaneous rupture of the left gastric artery with a hæmatoma in the gastrophrenic omentum in a female aged 64 with a history of hæmorrhages (nasal ocular).

Buchbinder and Greene (1935)—Spontaneous rupture of a gastric artery in a male aged 57.

Moorehead and McLester (1936)—(1) Spontaneous hæmorrhage from junction of right and left gastrics both vessels being severely diseased. (2) Spontaneous rupture of an aneurysm of the superior mesenteric artery. The respective ages were 44 and 50 years.

From a study of the recorded cases two facts emerge: (1) hypertension is an invariable accompaniment. (2) the age-incidence is between 44 and 60 (average 52). In only one case is there positive evidence of aneurysm formation and on this account the next case which I am reporting is of interest. I am able to include it through the kindness of Mr C F W Illingworth under whose care the patient was

CASE 3.—For some days the patient, a man of 75 had complained of being slightly off colour. Before this he had had some difficulty in securing regular evacuation of the bowel and had required a daily aperient. On the day of admission he was seized with sudden pain in the upper abdomen and for some hours this was attended by repeated vomiting of food material. When examined after admission he was found to have a subnormal temperature and a feeble rapid pulse. His tongue was dry and furred and he looked ill. Investigation of his abdominal condition revealed a prominent ballooned and tender cæcum; the tenderness was continued over the whole distribution of the colon but there was no rigidity and no swelling could be detected. There was dullness in both flanks and a diagnosis of acute obstruction supervening on a chronic malignant obstruction was made.

At operation a massive intraperitoneal hæmorrhage was disclosed, a swelling could be discovered on palpation apparently in relation to the aorta and was taken to be an aneurysm and the abdomen was closed without drainage. The patient died a week later from broncho-pneumonia and post mortem examination showed an extravasation of blood in the general peritoneal cavity and in the transverse mesocolon. An aneurysmal dilatation was present on the middle colic artery and was the source of the hæmorrhage. The abdominal vessels were normal and the aorta itself showed only slight atheromatous changes with some degree of thickening of the aortic valves.

At first sight it seems most likely that the aneurysm in this case was secondary to arterio-sclerotic vascular degeneration. Yet the remainder of the abdominal vasculature was healthy. It is a fact nevertheless that abdominal aneurysm can occur in the absence of degenerative changes in the arterial wall for Budde (1925) has recorded a case of fatal rupture of an aneurysm of the left gastro-epiploic artery in a man of 27 without evidence of arterio-sclerosis.

In view of these findings it seems impossible to exclude as a possible cause of these aneurysms a congenital weakness of the vessel wall akin to that which leads to aneurysm of the basal cerebral arteries. Forbus (1930) in his classical account of congenital aneurysms has shown that they tend to form at the points of branching of the arterial tree and their occurrence is favoured by the special mode of formation of the arteries. In the development of an artery the larger trunks acquire a muscular coat while their smaller branches remain for a time as simple endothelial tubes. Later on the branches acquire muscular coats not as outgrowths from the muscle of the parent vessel but as independent

developments in situ from the surrounding undifferentiated mesenchyme. At the line of junction between branch and trunk the respective muscular coats meet, and should fuse solidly. It is in an imperfection of the latter process that the explanation of the aneurysm lies, for the persistence of a gap or the occurrence of a "weak joint" creates a *locus minoris resistentiae*, at which "blowing out," with the production of aneurysm, may occur.

The rupture of a congenital aneurysm has attracted most attention when the intracranial vessels are involved. Forbus himself has drawn attention to the possibility of a similar accident in relation to other vessels, and indeed his views of the origin of the lesion were based on his studies of the development not of the intracranial vessels but of the mesenteric vessels. Reports of multiple military aneurysms of this nature in the coronary and mesenteric vessels have been made by Eppinger (1887) and by Gee (1871), and in relation to the pulmonary vessels by Wilkins (1917), and the renal arteries by Forbus (1930).

While it is impossible to be dogmatic about the third case, the probabilities favour such an explanation in the case of Budde, in the cases of Hartley and MacKechnie, and in my own, it seems, in view of the comparatively early age and the other considerations, that the hæmorrhage may well have originated in a military aneurysm, or in a spontaneous rupture at one of the numerous junctional areas on the mesenteric arterial tree, and in these two cases the clinical course offers a similar contrast to that of the massive or apoplectic type of rupture, and of the "leak" in the basal cerebral aneurysm. The premise unfortunately cannot be held to be proved, but the suggestion is made here in the hope that it may lead to more detailed investigation if similar cases are encountered by others.

It may also be of interest to record the mode and results of treatment in hæmoperitoneum from vascular causes, as illustrated by the cases I have reviewed. In the arterio-sclerotic cases ligation of the bleeding vessel was undertaken and has always proved successful, whereas in cases where the bleeding point was not definitely established, and where no treatment was carried out, the patient died. Both cases of established aneurysm were fatal, but in one of the two cases in which definite aneurysm was not found the patient recovered.

CONCLUSIONS

In the female the likeliest source of spontaneous hæmoperitoneum is the pelvic viscera, especially the ovary and tube. In the male the most common source is one of the mesenteric vessels, and a systematic search for the bleeding point should be made, since ligation greatly increases the chances of survival.

I am indebted to Sir John Fraser for the opportunity of treating the first two cases and for permission to record them. I am also grateful to Mr Illingworth for permission to refer to his case.

DIAPHYSECTOMY IN ACUTE OSTEOMYELITIS*

By A. L. D'ABREU, Ch M Birm, F R C S Eng
 SENIOR ASSISTANT TO THE SURGICAL UNIT, THE WELSH NATIONAL SCHOOL OF MEDICINE, CARDIFF

LOWER death rates for acute osteomyelitis have been recorded by those who prefer conservative and limited measures to the old "gutter" operation (Holman 1934, Tyrrell Gray 1934, Greene 1934). This paper must not be misconstrued as an appeal for radical treatment. Since the disease is a systemic infection followed by a local lesion, death that in the acute stage is due to septicaemia or pyæmia will not be prevented by guttering, shaft resection, or amputation. Such measures indeed increase the burdens of a critically ill patient. When the local lesion predominates, suppuration in the metaphysis spreads outwards to form a subperiosteal abscess, this sequence usually precedes a true myelitis. In children and especially in infants extensive stripping of the periosteum may not cause necrosis, so adequate is the blood-supply from the nutrient vessels. Exceptionally, early medullary infection coincides with the periosteal abscess, but more usually myelitis develops later as an inward spread along the Volkmann's canals from the subperiosteal abscess, rather than as a direct extension from the metaphyseal pus (Starr 1922).

CRITICISM OF THE GUTTER OPERATION

It is difficult to believe that the gravity of acute osteomyelitis depends upon the rigidity of bone, firstly because of the ease with which pus finds its way into the subperiosteal space, and secondly because in children the disease though arising within more porous bone—because of its greater vascularity—is far graver than in adults. It is more reasonable to ascribe the serious signs and symptoms of juvenile osteomyelitis to rapid absorption of toxins from the marrow, for the blood-vessels in growing shafts are arranged in sinusoidal form to enable blood cells—and hence bacteria—to gain ready access to the general blood stream. Such blood spaces are not found in adult bones.

Sound treatment, as in the case of cellulitis, avoids operation until there is a subperiosteal abscess. At the first operation incision of this suffices, rest to the patient and complete immobilisation of the affected limb, preferably in plaster, follow. If at operation the bone is bleeding there is no need to

Right: radiogram two years after operation there is no deformity except for a little backward bowing.

FIG. 4 (Case 4).—Radiogram seven months after complete diaphysectomy of the fibula.

drill or trephine since this sign indicates a healthy marrow and the absence of myelitis usually the evacuation of the subperiosteal abscess will prevent marrow involvement. The gutter operation would only expose further bone to infection while it adds the risk of sequestrum formation. If however the bone does not bleed even after drilling extensive

INDICATIONS FOR DIAPHYSECTOMY

Successful shaft resection by removing the diseased area diminishes though does not always prevent sequestration and gives splendid drainage to the subperiosteal space. The risk of non regeneration in children has been exaggerated it can be prevented by care in the selection of cases (to be described later) in the technique and in the after treatment, where adequate and prolonged immobilisation is essential. The operation is unjustifiable in patients over 10 for regeneration is too uncertain in adult shafts or in infants when the most extensive periosteal

FIG. 3 (Case 3).—Left: radiogram five months after diaphysectomy showing an apparent pseudoarthrosis. Right: complete regeneration of fibula in eight months.

FIG. 2 (Case 2).—Portion of fibula removed.

stripping may not cause necrosis. In the fibula it is the operation of choice even to the exclusion of simple drainage for non regeneration is rare and does not prevent a good functional result and rapid healing.

CHOICE OF PATIENTS

Apart from osteomyelitis of the fibula, resection is unjustifiable until simple periosteal incision combined sometimes with metaphyseal drainage and followed by plaster case immobilisation has been tried. If the temperature persists after four days the wound is reopened and any abscesses drained. If however the periosteum is widely stripped the shaft is drilled by the technique described by Frazer (1934). If no bleeding follows the shaft is dead or occupied by pus and will form a large sequestrum.

guttering will not save it for its blood supply has already gone nor will it provide adequate drainage for the pus lies mainly without and not within the shaft; while sequestrum formation will not be prevented by so incomplete a removal if the shaft is necrosed. In such conditions shaft resection is superior to the gutter operation and may replace amputation.

6

FIG 6 (Case 5)—Radiogram a year after operation showing incomplete regeneration with pseudoarthrosis

7

FIG 7 (Case 6)—Abscess cavity in the centre of a shaft which shows chronic osteomyelitis

it should therefore be removed in preference to futile guttering. As already said, resection in the presence of an adherent periosteum is unjustifiable, for revascularisation of the shaft may follow.

THE CASE AGAINST DIAPHYSECTOMY

Greig (1933) correctly says that bone is at the mercy of its blood supply, being decalcified by the hyperæmia of infection. In acute osteomyelitis the liberated calcium is redeposited within the periosteum to form the new involucrum and failure

FIG 5 (Case 5)—Wound after partial diaphysectomy of fibula

of bone regeneration is to be expected after diaphysectomy as the available calcium is removed, he says the shaft should not be removed until new bone is well developed. Since dead and avascular bone does not readily yield its calcium the argument loses force, and even in the absence of a shaft the inflamed periosteum, already rich in calcium and osteogenic properties, rapidly lays down new bone.

Clinical Experience in Seven Patients

No account is given of the operation in the phalanges, metacarpals, or metatarsals but here I have seen successful results. In all instances diaphysectomy has been done before an involucrum had formed.

CLAVICLE

In my first patient, complete bone regeneration followed resection of an entire clavicle after periosteal incision and bone drainage had failed (d'Abreu, 1933).

CASE 1—In a boy of 14 with acute osteomyelitis of the outer end of the clavicle, a subperiosteal abscess—containing staphylococci—was opened. The temperature fell, but three days later the length of the clavicle was exquisitely tender. I operated again, found pus under the whole length of the periosteum, and performed complete diaphysectomy. Ten days later a large mass of callus was palpable. The patient, who had been immobilised with a long sand pillow between the scapulae, was then allowed to use the arm freely. A radiogram taken 22 days after the diaphysectomy showed a massive bone deposition. Five weeks after the operation the function of the upper limb was normal. Palpation revealed a normally outlined clavicle.

FEMUR

The second case is one of acute osteomyelitis of the femur with diaphysectomy followed by recovery and bone regeneration. (I am indebted to Mr Geoffrey Keynes for permission to include this patient upon whom he operated.)

CASE 2—A boy, aged 6, was admitted to St Bartholomew's Hospital with acute osteomyelitis of the lower end of the right femur, at 10 o'clock on the morning of admission the lower end of the femur was exposed and a subperiosteal abscess drained, but as at 7 p.m. on the same day he remained critically ill a second operation was performed. To save amputation most of the shaft of the femur was resected subperiosteally and a

8

FIG 8 (Case 7)—Resected portion of shaft. Note the drill holes through which pus was located at the second operation and the original window drainage of the metaphysis.

9

FIG 9 (Case 7)—Lateral radiogram of the regenerated tibia.

blood transfusion given, the wound was left widely open and irrigated by the Carrel-Dakin method, the pus contained staphylococci. The limb was carefully splinted with extension maintained by skin strapping.

Progress—Sixteen days after the operation measurement of both lower limbs did not detect any shortening or lengthening. A radiogram taken on that day showed

that new bone was being laid down (Fig 1). The extension was maintained for eight weeks at this stage on measurement the affected lower limb was 1 cm longer than the normal side; a radiogram showed good alignment and a newly formed shaft. Progress was extremely satisfactory although small sequestra had to be removed on three occasions a ring sequestrum being removed six months after operation one a year after diaphysotomy and the last a year and two months after the first admission.

Result.—He was seen in July 1930 when the wound was soundly healed and again in 1932 when he was a well-developed boy with a sound femur. Radiograms taken over a period of nine months after operation showed excellent bone regeneration (Fig 1).

Comments.—In the bone apparently most unsuitable for diaphysotomy owing to its inaccessibility its importance in weight bearing and lack of a companion bone an excellent result can be obtained. Great care in maintaining accurate extension and guarding against backward bowing prevented deformity. The operation was an excellent substitute for amputation, giving adequate drainage in a critically ill child. Diaphysotomy should have no place in the routine treatment of osteomyelitis of the femur but if after periosteal incision and drainage of the metaphysis has failed resection of an avascular shaft is preferable to extensive guttering or amputation. Rankin (1927) has published some splendid results in the femur after resection.

TIBULA

There is no safer or more humane treatment of acute osteomyelitis of the tibia than early excision of the affected bone and primary union of the wound may follow (see Fig 5).

CASE 3.—A boy aged 12 provided a typical example. He had severe pain over the lower end of the left tibia for five days before coming to hospital. On the day before admission there had been a rigor. There was a brownish red swelling over the tibia at its lower part.

Operation.—Through an incision over the lower third of the bone the peroneal muscles were displaced laterally and posteriorly. Pus was found between the periosteum and the bone for a distance of 2½ in. The bone was divided 3 in. above the epiphyseal cartilage and the lower portion of the diaphysis avulsed; it separated easily from the epiphyseal cartilage which was left behind and intact (Fig 2). The wound was lightly packed with vasoline and the limb immobilised on a splint.

Progress.—On the 10th day the wound was healthy; a light plaster cast having been applied he was discharged well and free from pain; the wound was completely healed within four weeks of the operation. He was allowed to walk three weeks after the operation the light plaster being discarded six weeks after admission.

Result.—A radiogram taken 10 days after the resection showed new bone. Six months later the shaft was almost completely re-formed but there was an appearance suggesting a pseudo-arthritis (Fig 3). The gap however disappeared and the bone regenerated completely (Fig 3).

CASE 4.—In a girl of 9 although regeneration was quite satisfactory after an extensive diaphysotomy (Fig 4) it was feared that since for some weeks she could not extend the big toe the external popliteal nerve had been injured at the operation but also recovered so rapidly that it was probably due to temporary removal of its origin of the extensor hallucis proprius. As the bone regenerated so the power of extension returned. The wound has remained soundly healed since operation.

Incomplete regeneration.—Although this was seen once there was no loss of function. This was in a boy of 11 (Case 5).

At operation pus was found subcutaneously and had burst through the periosteum which was found to be lifted from the bone; the lower quarter of the tibia was removed

and avulsed from the epiphyseal plate. The wound was wiped out with flavine and lightly closed. Progress was entirely satisfactory and the wound healed almost by the first intention, the boy being discharged 13 days after operation and allowed to walk (Fig 5). Bone regenerated imperfectly slowly and irregularly. An ominous gap existed two months after the operation. This gap though diminished still existed six months later. A radiogram taken a year after the operation showed permanent non union (Fig 6). Union is impossible without operation, but as there is no disability this is of course unjustifiable.

Incomplete regeneration is difficult to explain. Bigard (1935) has shown that resection of periosteum successfully prevents bony regeneration and at the operation on this boy I probably damaged a part of it. Lortholair (1935) also comments on the necessity of preserving the integrity of the periosteum and refers to unsatisfactory results following its damage.

Adults.—Since non regeneration is not satisfactory in adults diaphysotomy should not be carried out in these on any bone other than the fibula. The operation has been done once in an adult.

CASE 6.—A man aged 23 complained of painful swelling in the mid shaft of the left fibula. When he was 15 years of age he had severe pain in the leg for a week which was treated by hot fomentations until an abscess formed and broke; this abscess took six months to heal. After that he had several recurrences of pain and of discharge. There was a fluctuant swelling half way down the fibular shaft the whole length of which was enlarged. A radiogram showed a Brodie's abscess situated in the mid-shaft (Fig 7).

Operation.—A subcutaneous abscess was opened and led down to greatly thickened bone; the portion of bone containing the abscess was removed and after the wound had been lightly packed with vasoline gauze the leg was immobilised in a plaster cast.

Result.—The wound healed well. There has been no bone regeneration but function is normal.

Comments.—In these cases of shaft resection of the fibula the disease was rapidly arrested. Sequestrum formation avoided and rapid healing obtained.

TIBIA

The following is a case of osteomyelitis of the tibia in which metaphyseal drainage was performed followed later by diaphysotomy. It resulted in regeneration with some sequestrum formation.

CASE 7.—A boy aged 12, had had severe pain above the right ankle for some days. He was extremely ill flushed and restless with a temperature of 102½ and a pulse rate of 112.

First operation.—The lower third of the subcutaneous surface of the tibia was exposed. On incising the periosteum only a little pus escaped and a window of bone over the metaphysis was removed and pus was found in the marrow above the metaphysis was healthy and bled normally. The wound was lightly packed with vasoline gauze and the limb enclosed in a plaster cast from above the knee joint to the heads of the metatarsals.

Since the temperature and pulse-rate remained high on 1 the boy was still ill a second operation was performed (eight days later).

Second operation.—The plaster cast was removed the wound was extended upwards and an incision was found under the periosteum reaching up to the proximal half of the tibia. The tibia was drilled in three places. From the lower two holes pus exuded but healthy bleeding came from the highest bone puncture. Because of the extensive spread of pus both within and without the shaft extensive necrosis appeared inevitable and more than two-thirds were resected. The wide separation of the periosteum from the shaft made the use of a respiratory unnecessary. The bone separated easily from the lower epiphyseal cartilage (Fig 8). To prevent collapse of the tibia

periosteal tube, a glass rod was placed in its cavity. The wound was lightly packed with vaseline gauze and the limb encased in plaster.

Progress—With the temperature and pulse rate rapidly falling there was a marked improvement in the general condition. A radiogram taken 14 days after the operation showed new bone around the glass rod which was then removed under general anaesthesia. When the plaster had been removed the large wound looked healthy, the glass rod was lifted out and the whole limb again immobilised in plaster. The further progress was satisfactory, dressings being done at monthly intervals with the limb rigidly immobilised throughout in plaster. At the sixth dressing sequestra were removed from the upper and lower ends of the wound, the former being a ring sequestrum. At that time the shaft was well regenerated. The boy was discharged on Sept. 29th in a plaster to which was attached a Böhler's walking iron, the wound was not completely healed, but is now quite sound.

Result—As seen on radiograms bone was being reformed as early as on the fourteenth day after the diaphysectomy. Two months after operation a new shaft had reformed. The lower part at this stage was not so well regenerated as the upper. This deficiency coincided with a good deal of residual infection in that area and was no doubt due to the decalcifying effect of a local hyperaemia. Six months after diaphysectomy there was further bone formation to be seen on the radiogram. At this stage a sequestrum had appeared and was removed. Fig. 9 shows a lateral radiogram of the newly formed shaft, although a cavity is present this is symptomless.

Summary

Diaphysectomy is rarely required in the treatment of acute osteomyelitis since the results of conservative incision of a subperiosteal abscess are good when combined with general and local rest, in common with other radical measures it is unavailing when fulminating septicaemia overshadows the local lesion.

Extensive periosteal stripping does not imply certain necrosis, but when combined with true myelitis the shaft will largely die, in such patients resection diminishes sequestrum formation and provides splendid drainage of the pus in the periosteal tube. The gutter operation is unsound for it does not save sequestration nor provide adequate drainage, it is based on the faulty assumption that bone rigidity is the important factor in acute osteomyelitis. The theoretical objection that a valuable source of calcium is removed by diaphysectomy overlooks the inability of avascular bone to yield or acquire calcium. The operation is unjustifiable in infants and in adults, the optimum age being from 6-16. The procedure, except in the fibula where it is the operation of choice, must not be adopted until simple periosteal and metaphyseal drainage have failed and then only when there is certain proof of myelitis. An adherent periosteum requiring instrumental separation contraindicates resection.

The results in seven patients have been satisfactory. The epiphysis must be conserved and the resection need not proceed 1 inch beyond the affected portion of the shaft. The periosteum must be meticulously preserved from damage and adequate immobilisation provided.

MEDIASTINAL GANGLIO-NEUROBLASTOMA

By F DUDLEY HART, M.B. Edin

MEDICAL REGISTRAR AT THE ROYAL NORTHERN HOSPITAL, LONDON AND

P O ELLISON, M.B. Lond

PATHOLOGIST TO THE HOSPITAL

In 1870 Loretz discovered a tumour containing well differentiated ganglion cells, and so established the occurrence of neoplasms to which the term ganglioneuroma was applied. Later, as a result of further study of such tumours and increased knowledge of the anatomy and development of the sympathetic nervous system, tumours were recognised which were composed of undifferentiated sympathetic formative cells. Such tumours are now called neuroblastomata. In between these two extremes (benign and actively malignant) all degrees of intermediate tumours were found, and Landau (1912) and von Fischer (1922) have classified them under a variety of different headings. Such tumours, although commonly arising from undifferentiated sympathetic tissue in the region of the adrenal medulla, may also arise elsewhere from sympathetic nerve tissue in the abdomen, thorax, brain, cranial and peripheral nerves, and elsewhere. The neuroblastoma is well recognised, and descriptions of the Pepper and Hutcheson types can be found in all comprehensive text-books of paediatrics. The ganglioneuroma is uncommon, but is carefully described. The intermediate forms are rare, and so little attention has been given to them in this country that the present case is thought worthy of detailed description.

CASE REPORT

A boy, aged 6, was admitted to hospital on Jan. 25th, 1937, complaining of pain in the abdomen on and off for one week, pain in both knees and the left side of the face for one week, and small glands in the neck, painless and discrete, for four weeks. Previously he had been unwell for about a month. There had been no definite tonsillar infection noted. The pain in the knees was not acute but was made worse by movement. He had failed to gain weight for four months before admission. There was no history of cough, fever, or acute systemic upset. He had slept well, remained fairly cheerful, and had a normal appetite until one week before admission. He had had measles and chicken pox over a year ago.

Examination—Temperature 102.7° F., pulse rate 124, respiration rate 26. A thin boy, somewhat flushed but quite cheerful. Small discrete glands very slightly tender both sides of the neck. Left tonsillar gland enlarged. Small shotty painless glands in both axillae. Examination of cardiovascular and respiratory systems revealed nothing definitely abnormal. Abdomen slight tenderness in both iliac fossae, but no rigidity, liver and spleen not palpable. Joints slight pain experienced on moving both knees, also left hip, otherwise no apparent abnormality. Central nervous system normal, no rash. Blood white cells, 8000 per cmm (polymorphs 54 per cent, lymphocytes 40 per cent, mononuclears 6 per cent), no abnormal red or white cells seen. Mantoux negative 1 in 10,000, 1 in 1000, and 1 in 100.

Progress—The temperature came down to normal in four days but occasionally rose to 99°-100°. Pulse and respiration rates also fell correspondingly. On Feb. 16th temperature rose to 100.4°. Pains in the neck. Glands much as before, but slightly more tender. Throat normal. Blood white cells, 6000 per cmm (polymorphs 60 per cent, lymphocytes 32 per cent, mononuclears 7 per cent, basophils 1 per cent), 4 myelocytes and 2 normoblasts per 200 white cells. Sedimentation rate

53 mm in 1 hour (microscopical method). The urine presented no abnormalities. The temperature had settled by Feb 22nd when a radiogram showed an oval mass behind the heart alongside the vertebral column in the posterior mediastinum (Fig 1). Feb 25th; blood picture as before, general condition improved.

On March 6th he was very restless, with acute pain in the left knee. Movements free and painless at the knee, but much pain experienced on attempting to move the left hip, where the muscles were in spasm. Adduction, abduction, and flexion all equally painful. Nothing abnormal noted in the spine. Spleen not palpable. Left leg was put in extension. He rapidly improved but an intermittent pyrexia persisted. Temperature 100.2. Pulse-rate 180. Later (March 12th) he had acute pain in the other hip with similar findings.

Operation by Mr F. D. Saner under general anaesthesia. March 18th. Left side of chest explored with a needle. No fluid found but some resistance offered to the needle. A portion of the ninth rib was removed and an encapsulated tumour removed without difficulty from the posterior mediastinum. It was extrapleural with no adhesions bar

cytoplasm; they vary somewhat in size and shape and on careful search all stages between the small undifferentiated cell and the large pale ganglionic cell can be found. In addition rosette forms consisting of small deeply staining coils arranged peripherally around a fine fibrillar stroma are well shown (Fig 5). The tumour therefore shows features of both neuroblastoma and ganglioneuroma and is best described as ganglioneuroblastoma.

Further progress.—On March 23rd he was recovering from the operation. Pale. A blood count showed: haemoglobin, 45 per cent; red cells 2,600,000; colour index 0.8; reticulocytes 3 per cent; white cells 7000 (polymorphs 60 per cent; lymphocytes 29 per cent; mononuclears 6 per cent; eosinophils 4 per cent; basophils 1 per cent); 4 megakaryoblasts; 1 normoblast; 3 myelocytes and 1 myeloblast per 200 white cells; many hypochromic red cells; some anisocytosis and polychromasia.

May 3rd: the child is still anemic, but is cheerful, happy and free from pain. He has latterly been allowed up and walks well. He occasionally gets slight pain in the left knee as before. His haemoglobin 65 per cent on April 23rd is now 65 per cent. His red cells had risen as high as 4 millions per cmm. but have now dropped to 73 millions. His colour index has varied from 1 to 0.7. Immature red and white cells persist as before. Radiography has shown nothing abnormal in the hips or spine. It was thought his spleen could be felt following the

FIG 1.—Radiogram (antero-posterior) showing mass in mediastinum partly obscured by shadow of heart.

FIG 2.—The tumour cut in half showing the pale outer ganglioneuromatous part and the malignant inner core of neuroblastomatous tissue.

a few loose connexions to the surrounding structures. It was lying alongside the vertebral bodies opposite thoracic vertebrae 7-11. There were no definite connexions at its lower pole.

Pathology.—The tumour was encapsulated with a firm yellow white cortex and a red "medulla" which in places came near the surface. Irregular in shape 2½ in. long 1½ in. wide 1½ in. thick (Fig 2). Paraffin sections were prepared from the solid outer portion of the tumour and from the adjacent haemorrhagic area. The stains used were Ehrlich's haematoxylin, Anderson's iron haematein, orxlin and eosin and van Gieson as counterstains. The outer portion of the growth shows a groundwork of very fine longitudinal fibrils accompanied by flattened nuclei running in the same direction. This tissue is arranged in rather ill-defined bundles with loose connective tissue between them. Somewhat sparsely scattered throughout there are collections of pale staining cells without any definite arrangement (Fig 3). Some of these cells are very large others quite small and there are many intermediate forms. These features are characteristic of a ganglioneuroma and it may be noted that the resemblance to sections of sympathetic nerve ganglia is striking though of course the histological picture is not absolutely identical.

The central portion of the tumour shows an active neoplastic process, accompanied by haemorrhage and necrosis. The growth consists of deeply staining cells arranged in masses of varying size (Fig 4). The cells themselves are small and rounded and contain very little

FIG 3.—Outer part of tumour. Section shows large cells resembling those of ganglioneuroma. (x 250.)

FIG 4—Central part of tumour showing large pale pre-ganglionic cell and small deeply staining undifferentiated cells ($\times 380$)

transfusion, but at no other time. The glands on the right side of his neck are definitely larger now. His central nervous system seems normal. A histamine test-meal reveals no abnormality. His temperature occasionally rises and falls over an 8-18 day period (Fig 6) and is normal between, with occasional rise in the evening to 99° - 99.7° .

Other treatment—He has had one blood transfusion, and is having a liver extract and iron.

DISCUSSION

The case is of interest because, although the tumour is malignant, histologically and clinically, it comes half way between the benign true ganglioneuroma and the highly malignant neuroblastoma, and corresponds to the ganglio neuroblastoma of Robertson (1915) or the neuroblastoma gangliocellulare of von Fischer. In the section the cells of different stages of development are well seen, small round cells resembling small lymphocytes, larger cells resembling large lymphocytes with vesicular nuclei, and even larger cells running up to immature ganglion cells. These cell types correspond to the sympathogonia and sympathoblasts described by Wright (1910). Such a tumour is usually discovered later than the highly malignant completely undifferentiated neuroblastoma, and sooner than the benign ganglioneuroma which may, indeed, be entirely silent and discovered unexpectedly at autopsy. Metastases occur, but the whole picture is a slower, gradual one.

In this case metastases have almost certainly occurred. The X ray appearance suggests a cord of

tissue running to the region of the left adrenal. Pruns in the lower limbs were noted in some of the cases described by Frew (1911), and Stout (1924) described a case of a child, aged 21, who complained of weakness in the legs. Death followed attempts to remove a left-sided adrenal ganglio neuroblastoma and an ingrowth was found passing from the tumour through the intervertebral foramen to cause compression of the cord. The leg pruns in the case described here may be due to a similar cause.

The anaemia is of interest. It differs from the simple microcytic anaemia usually described in such cases in having many immature red and white cells in the circulation and many large red cells. The colour index has varied from 0.7 to 1. It appears to be a leuco erythroblastic anaemia, possibly due to secondary deposits in bone. In view of the potential malignancy of these tumours, even the more benign form early removal is indicated. Even so, the prognosis is bad in this case.

The radiological findings allowed an early diagnosis to be made. In a straight antero posterior view

FIG 5—Cells arranged in rosette form ($\times 380$)

nothing was seen at the normal density as the tumour was hidden behind the heart. An oblique view, however, revealed it, and lateral and hard antero posterior pictures revealed the true extent and size of the mass. Such a large mass, however, gave no definite physical signs, and the X ray reports came as a surprise. There is no radiological evidence of metastases in the bones, but the glands in his neck are increasing in number and size, and it is likely that they are secondary to a lymphatic spread.

Our thanks are due to Dr Bernard Schlesinger for his permission to publish this case and for the great help he has given us.

CLINICAL AND LABORATORY NOTES

PANCREATIC CANCER WITH DIABETES

By F. PIGOTT M.B. Liverpool D.P.H.

LATE ASSISTANT RESIDENT MEDICAL OFFICER, MILL-ROAD INFIRMARY LIVERPOOL

AND THE LATE

H. OSBORN D.M. Oxon, D.P.H.

PATHOLOGIST TO THE SOUTHERN GROUP LIVERPOOL MUNICIPAL HOSPITALS

CANCER of the pancreas and diabetes mellitus are common diseases in medical practice but it is rare to meet both in the same patient. The usual sequence is for the cancer to supervene on the diabetes for clearly there is no reason to think that a diabetic is any less liable to develop cancer of the pancreas than an ordinary person. In the patient whose history is given below this order was reversed and the diabetic state was the result of the pancreatic neoplasm.

Malignant disease of the pancreas most often affects the head and/or body of the gland leaving the tail which contains the greater part of the islet tissue uninvaded until a very late stage. Hence the symptoms are the outward expression of biliary and pancreatic obstruction and not of disturbed carbohydrate metabolism. A neoplasm commencing in the tail of the pancreas would not be likely to give rise to any obstructive signs or symptoms but rather would show itself by an upset in the carbohydrate balance.

The frequency of carcinoma of the tail of the pancreas is about one thirtieth that of the rest of the gland. Ewing (1928) collected 358 cases of cancer of the pancreas and in 12 of these the disease was primarily confined to the tail. Fletcher (quoted by Osler) recorded 58 cases of pancreatic new growth among 42,000 admissions to the Johns Hopkins Hospital, the diagnosis being confirmed in 31 cases at autopsy. On this basis one would expect one case of cancer of the tail of the pancreas in about 30,000 hospital admissions.

CASE HISTORY

The patient was a printer aged 58. For three or four months before entering hospital he had been working in another town some distance from his home. During this time he noticed increasing lassitude followed later by a sense of complete exhaustion. He said that at the beginning of this period he had had slight swelling of the legs lasting for a few days. For six weeks his thirst had greatly increased and he had suffered from severe polyuria. His appetite was very poor and he had lost weight. For the last month he had noticed that he had a small swelling in the left side of his neck and that his voice had become hoarse. He gave a history of pneumonia and pleurisy four years before.

His nutrition was very poor. He had that laxity of the skin which follows intense dehydration and loss of weight. There was no icterus of the skin or conjunctiva; no oedema of the ankles and moderate clubbing of the fingers. There was no smell of acetone in his breath. His pulse rate was raised (100 per minute) but his temperature and respiratory rate were normal. He had a small ovoid swelling in the left lobe of the thyroid which had caused a slight deviation of the trachea to the opposite side. His peripheral arteries were moderately sclerotic. No abnormal physical signs were made out on systematic examination. A specimen of his urine freely reduced Fehling's solution but contained no acetone or diacetic acid. A quantitative analysis the following day showed 2.5 per cent of glucose and a later examination

3.5 per cent. The fasting blood-sugar was 250 mg per 100 c.c.m. on the day after admission.

Sputum examination was negative for tubercle bacilli and X ray films of the chest revealed no abnormality. Unfortunately he was not well enough to submit to a laryngoscopy. He was put on to a diet of milk, 7 oz four hourly with water ad lib. No insulin was given. His lack of appetite and poor general condition prevented the addition of solid food to the diet. He was entirely confined to bed. Soon after entering hospital he complained of abdominal pains which were not severe at first but later increased in intensity. Nothing apart from slight generalised abdominal tenderness could be found to account for them. His bowels were acting normally. On the seventh night after admission he was kept awake by an intolerable desire to have a bowel action. In the early hours he called for a bed pan suddenly began to sweat, collapsed, and died.

An autopsy was performed the same day. A large mass, the size of a grape-fruit, occupied the site of the tail of the pancreas; the head and body were not involved. The left lateral portion of the tumour was necrotic and a loculated cavity had been formed by adhesions between it and the splenic flexure of the colon, and a portion of the peritoneum of the lesser sac. The cavity was filled with old and recent blood clot. The left kidney had two small secondary deposits beneath the capsule. The liver was normal and there was no biliary obstruction. The thyroid was enlarged mainly on the left side due to secondary metastases. The larynx was normal in appearance. The lungs were oedematous and the heart showed some degree of myocardial degeneration.

Microscopic sections of the primary growth and of the secondary deposits in the kidney and thyroid showed the same characters. Dr Osborn's report was: "The histological appearances are typical of the more embryonic type of carcinoma of the pancreas, having a superficial resemblance to lymphosarcoma. The cancer cells are small, darkly staining with little cytoplasm and arranged loosely in masses. The islets in the adjoining portion of pancreatic tissue seemed normal in structure."

HISTORICAL SURVEY

Gerard Kissel and Pötty (1932) record a case of moderately severe diabetes with pancreatic deficiency in a male aged 45. At autopsy the pancreas was one mass of growth and metastases were present in the liver, left kidney, colon and mesocolon. Army Jones and Wood (1931) describe a case of diabetes with fatty diarrhoea due to carcinoma of the pancreas. Velazquez (1932) records another case of pancreatic diabetes complicating cancer of the head of the pancreas.

The frequency of cancer of the pancreas in diabetics was studied by Marble (1934) who followed the after histories of 1000 diabetics. Of these 256 died of cancer—in 35 cases from cancer of the pancreas (21 were confirmed at necropsy). No case was found in which the head was not involved. In 4 cases the whole gland was affected but the tail to a less extent than any other part. In every case the neoplasm supervened on the diabetes.

Gibbs and Logan (1929) reported the results of 147 autopsies on diabetic patients. No mention is made of growth being found in the pancreas on any occasion. Incidentally they found apparently normal islets present in 11 cases.

SUMMARY

A case of diabetes mellitus and carcinoma of the tail of the pancreas is reported. The history and findings at autopsy make it clear that the diabetes was the result of the pancreatic new growth. Unfortunately the patient's condition did not allow

us to perform a glucose-tolerance test, which might have produced an interesting curve

We feel impelled to publish this case, not only because of its rarity, but also to stimulate interest in the collection of further post-mortem evidence in diabetes mellitus, a disease whose aetiology from a pathological point of view is still incompletely worked out

I greatly regret that owing to the untimely death of Dr Osborn it has been impossible to produce an adequate photomicrograph of the sections.—F P

THE USE OF STENT COMPOSITION IN RADIUM TREATMENT OF CARCINOMA OF THE VAGINA AND URETHRA

By CLIFFORD WHITE, F R C P Lond, F R C S Eng, F C O G

SENIOR OBSTETRIC SURGEON TO UNIVERSITY COLLEGE HOSPITAL LONDON

Excision of a carcinoma of the vagina or urethra is generally agreed to be a most unsatisfactory operation and one which can only be attempted in unusually early cases. The results of operative treatment have been so depressing that most gynaecologists now prefer to use radium, although the growth is not of a type which is usually very radio-sensitive. In using interstitial radiation for a carcinoma of the vagina by inserting radium needles of suitable length into the growth the immediate

difficulty is that only short needles can be used without a grave risk of penetrating the bladder, urethral canal, or rectum. An exception is when the carcinoma happens to be low on the posterior wall of the vagina, but this is rare and such cases are suitable for treatment by excision. Short needles inserted into vaginal growths almost always fall out even if the vagina is thoroughly plugged, and in the case of a carcinoma of or near the urethral orifice plugging is not feasible. Thus attempts have been made to secure the radium needles or the boxes containing the radium needles to the wall of the vagina or urethra by catgut sutures. This is technically not easy to do, as superficial sutures cut out of the tissues and deeply passed sutures may perforate the adjacent viscera thus accelerating fistula formation.

To avoid some of the above difficulties, I have used Stent's Dental Composition (Porro and Co, New Cavendish street, London, W 1) in some six cases during the last three years. The wax composition is heated till it can be moulded to the length and size of the vagina—a small senile vagina takes about one of the tablets and a capacious vagina will require three. Having thus got an obturator which fits the vagina from the cervix to the urethra, the radium needles are embedded into that part of the surface of the obturator which will be opposite to the growth—i.e., in the case of an epithelioma of the urinary orifice, the needles are inserted into the upper part of the external end of the obturator and may extend more to the left or right according as the spread of the growth is more to one side or the other. The whole obturator is then covered with a piece of rubber glove which is tied at both ends with thick thread, the ends of the threads are left long to facilitate removal of the obturator by traction on them. I have usually inserted 30 to 45 mg of radium element according to the size of the growth and given a dose of about 1250 milligramme hours which may be repeated. So far this dosage has not resulted in early fistula formation.

A self retaining catheter is essential

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF THERAPEUTICS AND PHARMACOLOGY

At a meeting of this section on June 8th, with Dr DOROTHY HARE, the president, in the chair, a paper on

Hyperthyroidism and the Thyrotropic Hormone of the Pituitary

was given by Dr ARNOLD LOESER (Freiburg i. Br.). He said that in animals the typical symptoms of hyperthyroidism could be produced by administering thyroid hormone or by increasing the production and liberation of thyroid secretion by giving the thyrotropic hormone. After injection of the thyrotropic hormone into a young guinea pig the thyroid showed definite changes. Macroscopically it was enlarged and filled with blood, microscopically there was a decrease in the amount of stainable colloid, with growth of the acinus cells which became first cubical and then columnar, the lumen of the follicles became smaller and the picture resembled that of the human gland in Graves's disease. The changes could be observed in from 30 minutes to 12 hours after the injection and were also apparent when living thyroid tissue was treated with thyro-

tropic hormone in vitro. The hormone was therefore believed to act directly on the gland cells, it was inactive when given by mouth and could be separated from other anterior pituitary substances, the growth and gonadotropic hormones. The hormone was estimated by the changes induced in the thyroid and had been found to be present in very different amounts in the pituitary of different species. Estimated in Junkmann Schoeller units per gramme the comparative figures were ox, 250–500, sheep, about 1000, rat, 4000–8000, pig, 300, horse, 70, and man 150–1000. The content in human pituitary gland was greater in patients suffering from tuberculosis and allied chronic infections than in those with other pathological conditions. The histological changes in the thyroid gland were accompanied by a reduction of iodine content, whereas the iodine content of blood and urine increased, after treatment with thyrotropic hormone the metabolic rate was also raised in guinea pigs and humans on the first day, but reached a maximum after 6–10 days, the glycogen content of the liver was lowered only after about four days, as it was after administration of thyroxine. Injection of thyrotropic hormone also caused hypertrophy of the adrenals and a fall in their vitamin C content, increased appetite, loss of hair, loss in weight, tachycardia, changes in

the metabolism of the heart muscle, and finally the characteristic tremor seen in humans. These symptoms were not observed in thyroidectomised animals. On the other hand exophthalmos could be produced in the absence of the thyroid and Marine and Rosen therefore thought that the thyrotropic hormone irritated certain centres in the mid brain which controlled the sympathetic nerve to the eye.

Many observers have been unable to maintain the high rate of production and excretion of thyroid hormone in normal animals. In fact all the changes except exophthalmos, retrogressed to normal or even subnormal even though the administration of thyrotropic hormone was continued. Lethal thyrotoxicosis was not produced, apparently because the thyroid became refractory to the hormone. Loeb in America had attributed this to an inhibitory action of the thyroid hormone acting on the thyroid to prevent further action of the stimulator. Certainly the simultaneous administration of thyroid substance reduced the effect of the pituitary hormone but according to Kuschinsky the thyroxine acted on the hypophysis. Dr Loeser pointed out however that hypophysectomised animals also developed a refractory thyroid under the continued influence of thyrotropic hormone. For this reason he concluded that there must be a second factor in which the pituitary played no part. Collip and Anderson had first shown that such a second factor existed. They had found that the blood of rats which had been injected for many weeks with thyrotropic hormone was able to inhibit the action of the thyrotropic hormone in another animal. The origin of this substance in the body was unknown but appeared not to be the pituitary thyroid adrenals or ovaries. This antithyrotropic principle had been found in the blood of rats guinea-pigs rabbits dogs, sheep and horses after 4-6 weeks treatment with thyrotropic hormone. It had also been found in normal blood of animals and man but not in thyroidectomised animals nor in Graves's disease. Loeser and Trikojus had succeeded in concentrating the antithyrotropic principle and obtaining a stable powder 25 mg. of which would suppress the action of at least 10 units of thyrotropic hormone. The extracts were active when given by mouth. Their action was not type-specific for the thyrotropic hormone from one species (cattle) could produce in a second species (sheep) factors which could suppress in a guinea-pig the activity of a thyrotropic hormone obtained from a third species (pig). The antithyrotropic principle was produced only if thyroid tissue or thyroxine was present. Inorganic iodine was without effect in this connexion. The principle was effective only against the thyrotropic hormone.

The refractoriness of the thyroid in pituitary hyperthyroidism seemed to be an adaptation process to protect the thyroid against the thyrotropic hormone. It might work by limiting production of the hormone and its excretion from the pituitary or by harring the thyroid from the effect of the thyrotropic hormone. In either way the over-excretion of thyroid hormone did not occur. Experimentally both were feasible for the excretion of hormone from the pituitary could be limited by giving thyroxine. Engagement of the thyroid might be achieved by a substance or substances normally present in the blood the amount of which might be increased in hyperthyroidism. The principle seemed to act directly on the thyroid. The thyrotropic hormone therefore had not only the property of activating the thyroid gland but owing to the enhancement of the latter's function of bringing counter-regulatory processes which protected the organism against further stimulation from

the pituitary hormone eventually reproducing the original state of the gland.

Dr Loeser had found however that the organism's dual capacity to protect itself could be broken through by giving progressively increasing doses of the pituitary hormone. In this way he had been able to maintain and develop the signs and symptoms of hyperthyroidism until death supervened. He had shown this by giving equal total quantities of pituitary hormone to two series of animals, one receiving uniform doses, the other doses which were doubled every three days until death occurred. In the first group moderate changes which retrogressed were developed. In the latter group the thyroids of all the animals were much enlarged being on average five times as large as normal. The adrenals were also enlarged and there was fatty degeneration and diffuse necrosis in the liver and kidneys. These effects were observed only when the hormone dosage was progressively increased and indicated a pronounced thyrotoxic damage since they were a feature of Graves's disease. Dr Loeser thought therefore that a continuous state of hyperthyroidism could be produced in two ways. The first was continual animation of thyroid activity with the normal protective function still preserved—i.e. true pituitary hyperthyroidism. The second was failure of the protective mechanism with a constant or increasing animation of thyroid activity. The possibility of treating Graves's disease with highly active antithyrotropic factor was worth consideration in certain cases.

Dr C. L. CORE said that the thyrotropic hormone was unfailing in its action. Since he first heard of it he had wondered what its relation was to the aetiology of Graves's disease. He had tried to find out whether the hormone circulating in the blood was increased in that condition. The serum of patients with Graves's disease appeared to contain an antithyrotropic effect. In order to discover whether the thyrotropic hormone appeared in the urine in Graves's disease he had developed a chemical means of concentrating it but even when large quantities of urine were used he had found no evidence of increased excretion. In the literature there was extraordinarily little agreement as to whether the hormone was present in the blood in Graves's disease; the balance of opinion seemed to be that if it were present it was rather below normal and that it was slightly increased in myxoedema. On the whole it seemed that the hormone was behaving more as a friend than a foe to man in Graves's disease. There was little evidence so far that in that illness the hormone was produced in excess or was an aetiological factor.

Dr RUSSELL BRAIN had been interested in cases of exophthalmos with ophthalmoplegia. In some of them the exophthalmos progressed after partial thyroidectomy although the basal metabolic rate was lowered. These observations supported the views put forward by Marine and Rose.

Dr A. W. SPENCE had been unable to find any evidence of increased thyrotropic hormone in Graves's disease or in two cases of spontaneous myxoedema. In the literature the results were conflicting. Graves's disease had been divided into two groups, the larger due to primary hyperthyroidism the smaller to hypersecretion of thyrotropic hormone. The serum of patients might serve as an indication for diagnosis and treatment; some workers claimed success from deep X-ray therapy on the pituitary. Dr Spence had found antithyrotropic substances to be present in normal serum but not in the serum of Graves's disease; he thought that that disease might be due to lack of inhibiting substance rather than to excess of thyrotropic hormone.

Mr A S PARKES, F.R.S., said that the term "anti hormone" had first come from Montreal. Its meaning was not clear and he preferred to speak of antithyrotropic serum. He asked Dr Loeser whether he had made immunological tests with that serum, to which Dr LOESER replied that he had not. Dr Parkes had been unable to find any antithyrotropic factor in the blood of six normal sheep.

Dr LOESER said he thought Graves's disease might be due to too much thyrotropic hormone or to too little antithyrotropic principle.

SOUTH-WEST LONDON MEDICAL SOCIETY

At a meeting of this society held at the Bolingbroke Hospital on June 9th, with Dr T A CLARKE, the president, in the chair, the Bolingbroke lecture was delivered by Dr CHARLES E LAKIN who took as his title

Physical Signs Are They Worth While?

Dr Lakin said that his experience as a teacher and an examiner had convinced him that physical signs were receding from the important position once held in the minds of students. Radiology was to blame, for with its increasing use physical signs were regarded as unreliable, and time spent in gaining proficiency in examination as wasted. To argue in terms of radiology *versus* physical signs was an error, since radiology only provided another set of signs, confirming those found on physical examination or supplementing them. The X ray apparatus could not be carried in the waistcoat pocket, and anyone who had studied under the old masters knew how much information and certainty could be attained through physical examination alone. Interpretation of radiograms was often difficult and sometimes misleading, and he quoted a case where a patient had been kept in bed for many weeks on the strength of an X ray shadow (thought to indicate fluid) at one lung base, when physical examination would have shown no evidence of a pleural effusion.

Physical signs revealed the physical conditions of the organ studied, for example the volume, density, expansibility, conductivity, and moisture of the lungs. To determine the nature of the process at work physical signs had to be correlated with morbid anatomy, another field of study now declining in importance. Dr Lakin agreed with Dr R A Young who had recently deplored the present tendency of the young physician to avoid post mortem work. The year 1761, he said, was notable for the publication of two books, the first being the five volume work of Morgagni then in his eightieth year, on the seats and causes of disease. The letters of which the book consisted gave accounts of the history, clinical condition, and post mortem findings of cases side by side. Dr Lakin read the account of a case of meningococci to illustrate the pleasant way in which the carefully observed facts were recorded. The book was the first real attempt to correlate post mortem findings with what had been observed in life, and marked not only the beginning of morbid anatomy, but the beginning of modern clinical medicine. Another book published in 1761 was a treatise in Latin on a new device for percussing the chest by Leopold Auenbrugger. The son of an innkeeper of Graz Auenbrugger applied to the human chest the principles of tapping on casks to determine their content. The published results of his seven years of observations on patients, checked in the post mortem room attracted little attention, although Stoll of

Vienna used the method. Corvisart, having read of it in Stoll's lectures, republished the book in 1808 with his own notes, and immediately percussion took its place as one of the most valuable clinical methods. Cullen (1784) was the first to write of percussion in England, but he never practised it. The reason for this neglect lay in the fact that the anatomical conception of disease had not crystallised. Physicians thought in terms of symptomatic nosology, similar symptoms of widely differing aetiology being grouped together. Corvisart extended the use of percussion to cardiac disease and aneurysm of the aorta, he first described the presystolic thrill of mitral stenosis. What the historians called the pathologico anatomical school of Paris, of which Corvisart was a distinguished member, was in reality a clinical school where the importance of correlating physical signs with morbid anatomy was recognised. Amongst the students attracted to Corvisart was Laennec, inventor of the stethoscope. Dr Lakin told the story of this discovery, based on the use of the transmission of sounds by solids in physical examination. Laennec's "*Traité de l'Auscultation Médiate*" (1818), filled with his own careful observations, was one of the greatest books in medicine. Another name to be remembered in this connexion was Joseph Skoda of Vienna. Trained in medicine, physics, and mathematics, he had applied the laws of sound to physical diagnosis, and had established physical signs on a logical basis with definite laws, to which faith could be pinned.

In the use of physical signs there were many difficulties, some, such as extreme scoliosis, being insuperable. It was possible to be much misled, but in only a small proportion of cases. In the vast majority physical signs could be relied on, and a method should not be discarded because it was difficult. The younger generation wanted results in a hurry without labour or sweat. It had to be remembered that radiologists had difficulty in interpreting radiograms, which often failed to elucidate difficulties. The logical basis of physical signs was that examination showed the physical condition of the organ examined. The next step was correlation with morbid anatomy. In a case with the signs of a cavity at the base of a lung, morbid anatomical experience showed that it would be unusual for a tuberculous cavity to appear at a base unless there was one higher up. Percussion gave information about lung density, solid lung giving a higher pitched note than spongy lung. A musical ear was necessary, especially as there was so little tone about percussion notes compared with those of musical instruments. A high pitched note resulted from solid lung or lung compressed by fluid. With fluid there was a greater feeling of resistance on the finger. Conductivity was tested by auscultation: the presence of bronchial or tubular breathing indicated solid lung, absent breath sounds that something intervened. Breath sounds arose in the larynx, solid lung conducting the sound better than spongy lung which gave vesicular sounds. Sometimes there was bronchial breathing over fluid, and in such anomalous cases the signs could be interpreted in the light of displacement of the apex beat. Expiration was prolonged when elasticity was lost as in emphysema. Cavernous breathing resulted from air passing over the opening of a cavity.

A great deal could be learned from the study of physical signs without X rays. Dr Lakin could not help wondering whether those who decried physical signs had ever got into the way of checking them. Perhaps they lacked a musical ear: perhaps they suffered from some defect of the organ of hearing.

SOCIETY OF MEDICAL OFFICERS OF HEALTH

At a meeting of the fever hospitals medical service group of this society on May 28th with Dr E H R HARRIS the president in the chair a paper on the

Heart in Diphtheria

was read by Dr H MASON LEETE (Hull City Hospital). Diphtheria, he said had been especially severe in Hull during the past six years and the numerous toxic cases gave opportunity for a study of the toxic myocardium. He had attempted to classify in a roughly quantitative manner the varying degrees of cardiac dysfunction. A clinical distinction was drawn between general toxic death in the first week of disease and cardiotoxic death in the second and third weeks. Changes in the relative intensities of the heart sounds could be recognised fairly constantly during the progress of a severe case together with extrasystoles and reduplications, and it was possible to place these phenomena in a scale which shows increasing or decreasing cardiac impairment. Proteinuria is an almost constant accompaniment in cardiotoxic cases.

Dr M. MITMAN (Eastern Hospital L.C.C.) said that Dr Mason Leete's clinical stages of diphtheria were substantially similar to his own. In the first week there was evidence of local lesions and general toxæmia, but electrocardiographic changes were rare. In the second week there was clinical and corresponding electrocardiographic evidence of cardiovascular damage in the more severe cases. Of the electrocardiographic signs the most common were changes in the form and voltage of the QRS complex changes in the direction of the T wave in significant leads and evidence of conductive lesions in the bundle and its branches. He believed that lengthening of the P-R interval was not common and that when damage to the main bundle occurred it produced a complete heart-block. Complete heart block sometimes occurred with a normal pulse rate. An indication of serious cardiovascular damage could be obtained not only from the quantity of albumin in the urine but also from the diminution in the quantity of urine passed. He believed that the cardiovascular phenomena in the paralytic stage as well as the paralysis themselves were of central nervous origin. He had inquired of physiologists if the cardiac irregularities and the tachycardia of this stage could be due to damage to the central nervous system and had been assured that they could.

Dr H S BANKS (Park Hospital L.C.C.) said that of the various factors concerned in the production of the heart lesion in diphtheria not the least important was the dosage and route of injection of the antitoxin. He noted that none of Dr Leete's cases had received more than 60 000 units of antitoxin some as little as 10 000 units divided between the intramuscular and the intravenous routes. The division of the dose in this way was in his opinion unnecessary and wasteful. The effective dose in toxic diphtheria was the intravenous dose and he advocated larger intravenous doses as a means of preventing or modifying the heart lesion. He knew the financial and mechanical difficulties involved in such a system of dosage but believed that it paid handsomely. He asked whether any member had followed up the late W. E. Dixon's work on the prevention of the heart lesion by preliminary administration of large doses of digitalis. He had not so far been able to determine what cases, if any were suitable for this method.

Dr E JAMES (Romford) expressed the view that gravis strains were not always responsible for a high case fatality. In a series of some 800 cases of diphtheria admitted to hospital from Dagenham Horn church, and Romford during the past 2½ years approximately 70 per cent. were classified as gravis and 20 per cent. as intermediate strains, yet the latter had been nearly twice as lethal as the gravis. What was the explanation?

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION

At a meeting of this society on May 28th with Mrs E C LEWIS the president, in the chair a paper on

Recent Advances in Obstetrics

was read by Miss KEREY PARKES. She said that in no branch of medicine did practice vary so much among reliable authorities as in obstetrics. New principles were very slow to be universally established and what was taught as an advance in one school might be condemned wholeheartedly in another. But during the last few years some important changes of outlook had been very general. For instance in the study of the toxæmia of pregnancy a subject always abounding in theories there was now an emphasis on the primarily metabolic nature of these disorders any actual toxins being considered as only the result of the disordered metabolism. In the treatment of minor degrees of disproportion in primigravidae the fashion for surgical induction during the last month had given way to the almost universal practice of trial labour at term with the lower segment Cesarean operation to follow if necessary. In general the overwhelming importance of the conduct of labour itself was gaining recognition now that the first enthusiasm for antenatal care had subsided. Even the most skilled and thorough antenatal treatment could not avoid all the dangers and difficulties to be dealt with during the course of labour. For purposes of discussion clinical obstetrics could be divided into the antenatal intranatal and postnatal periods.

ANTENATAL

Antenatal care could not be limited to the nine months of pregnancy since the woman's adjustment to this would depend on the state of her health and nutrition for years past. The province of the antenatal doctor thus covered almost the whole field of medicine. For early diagnosis the Aschheim Zondek and the Friedman tests had a high degree of accuracy and had other uses notably in diagnosing the intra-uterine death of a foetus the presence of a vesicular mole and the onset of chorion-epithelioma. A state of pregnancy having been diagnosed the next problem was to maintain it. In cases of repeated abortion extracts of corpus luteum were now given. Since this extract was unfortunately still very expensive an alternative method was to give large doses of a substance stimulating luteal activity which was found in the urine of pregnant women marketed as Antultrin or Progynon. Pregnancy being well established there were three main objects in antenatal work. (1) the avoidance of difficult labour due to malpresentation and disproportion (2) the avoidance and treatment of toxæmia, (3) the education of women in mothercraft and the hygiene of pregnancy. In each of these fields there had been some advance.

(1) By means of X rays in *pelvimetry* it was now possible to compare the actual diameters of the pelvis and of the foetal head. Unfortunately estimates based on these elaborate measurements were all static and failed to allow for the alterations in flexion and the moulding of the head which took place under the influence of uterine contractions, whose strength and efficacy were quite unpredictable. In cases of *breech presentation* external version was now undertaken slightly earlier than used to be the custom—from 32 to 34 weeks, instead of from 34 to 36. Where version failed and the legs were extended, it was no longer customary to bring down a leg when pelvic measurements were normal unless there was delay in the second stage. In cases of acute hydramnios where X rays revealed a normal foetus the tension of the liquor caused severe abdominal pain. It had been found possible to tap the amniotic sac through the abdominal and uterine walls, if necessary on several occasions, without disturbing the pregnancy.

(2) The *toxæmias of pregnancy* were now regarded as arising primarily from disturbed metabolism. The best protection against toxæmia was a good mixed diet, containing fresh foods, with plenty of iron, calcium, and vitamins, but it was still necessary to be constantly watching for early signs of toxæmia. Routine urine tests and blood pressure readings were now the rule, but in the estimation of oedema an interesting advance had been the recognition that much help could be obtained from regularly weighing patients, "occult oedema" being revealed by excessive gain in weight. It appeared from Dame Louise McIlroy's work that the normal gain was greatest from the 24th to the 28th week, being on an average 3 lb., while in toxic cases the maximum gain occurred rather later, from the 28th to the 32nd week, and was about 4½ lb. Miss Grace Jones had drawn attention to the state of the retinal arteries as an index of the condition of the arterioles elsewhere in the body, particularly in determining when the changes were such that permanent renal damage was likely to result. Any sign of retinal exudate or hæmorrhage was an indication for the immediate induction of labour.

(3) Great changes were going on in the *maternity and child welfare services*. The supply of domestic help was an aspect of domiciliary midwifery which did not, Miss Parkes thought, always receive the attention it deserved. A supply of reliable home helps under the supervision of the local authority, who would guarantee them an adequate wage, would go far to encourage women to be delivered at home.

INTRANATAL

As to the intranatal period, the general trend was to minimise interference of every kind, and to realise that the passage of the head through the pelvis was a dynamic problem—i.e., the uterine forces were quite as important as the relative sizes of passage and passenger. A few years ago the induction of premature labour was very popular for cases where disproportion was feared at term, but now induction had no place in the treatment of primigravids with suspected disproportion. Doubtful cases of disproportion should all be submitted to a trial labour at term. If after some hours of good pains and rupture of the membranes the head was not satisfactorily in the pelvis, Cæsarean section must be performed. The lower segment operation could safely be undertaken much later in labour than the classical operation. The routine use of anaesthetics in labour was becoming more general, and for the normal delivery self administration of gas and air was considered

best in combining safety and efficiency. Anaesthetics were important as a possible factor in the production of the condition known as "obstetric shock," a sudden and alarming collapse. The most effective treatment appeared to be intravenous saline, with stimulants such as Coramine or Icoral, and warmth. One complication of labour which had received more attention lately was the contraction ring, which occurred in otherwise perfectly normal cases, causing prolonged delay, and ultimately obstructed labour. It might arise at any stage of labour. When this was diagnosed early in the first stage the treatment was lower segment Cæsarean section. Later, when infection had occurred and the child was dead, morphia, deep anaesthesia, and constant traction by weights attached to the perforated head were the only methods available to relax the ring. Should the contraction occur only in the second stage, delivery might be accomplished by forceps under deep anaesthesia, and with amyl nitrite. In the third stage, when fortunately the complication was rare, treatment was by manual removal of the placenta after dilatation of the ring—a very difficult procedure. In the intranatal period the baby also had to be considered. The resuscitation of the shocked or asphyxiated baby by lobeline had recently been recommended.

POSTNATAL

Finally, speaking of advances in the puerperal period, Miss Parkes referred to prophylaxis against sepsis, the importance of droplet infection, of septic foci in the patient herself, and of conditions such as tonsillitis or ear discharges in other members of the family, when the mother was being delivered in her own, often overcrowded home. Hæmolytic streptococci were now known to be the important organisms, but had been differentiated into twenty-two different types, varying in virulence, the eleventh being the worse. Prontosil Album (*p* aminobenzene-sulphonamide) seemed to be an effective drug against hæmolytic streptococci, and its use provided an enormous advance in treatment. A complication which might arise during treatment with this drug was sulphæmoglobinæmia, which was manifested by cyanosis, especially of the lips, without any cardiac or respiratory distress. The condition appeared to be harmless as long as prontosil was stopped as soon as the cyanosis was noticed. Epsom salts should not be given to patients on prontosil, nor, in fact, any drastic purgative, for even those not containing sulphur increased the sulphides in the bowel by their irritating action. Another drug fostered by Queen Charlotte's was the widely used antiseptic Dettol.

An electrically driven breast pump was a fairly recent innovation, and increasing interest was being shown in the reconditioning of weakened abdominal and pelvic muscles by massage and exercises. More practical advice was being given to women about the proper spacing of their pregnancies, and patients with heart or kidney disease were given careful instruction in birth control rather than a vague statement that they must not have any more babies. The available clinics giving advice on contraception were still woefully overworked and overcrowded, and there were large areas without any, but the need for them was being recognised, and their numbers were increasing. Miss Parkes illustrated her address with some Kodak films of a type of lower segment Cæsarean operation, of difficult cases of breast feeding, and of a case of pseudo pregnancy, showing the disappearance of the phantom tumour under anaesthesia.

REVIEWS AND NOTICES OF BOOKS

Diseases of the Eye

A Text Book for Students and Practitioners By
EUGENE WOLFF M.B. B.S. Lond. F.R.C.S. Eng.
Ophthalmic Surgeon Royal Northern Hospital
Assistant Surgeon Royal Westminster Ophthalmic
Hospital, London Cassell and Co 1937
Pp 234. 15s

It is not easy to write a short text book on any branch of medicine or surgery. One of the main disadvantages of compression is the elimination of discussion of controversial points for the dogmatic statements which replace them do not always accord with clinical experience or current hypothesis. On the whole Mr Wolff has shown judgment in his choice of subject matter and has wisely abstained from confusing his argument by the inclusion of rare conditions and variations. To those who find diagnosis of the normal more difficult than that of disease the well written chapter on the fundus is commended. The author has wisely refrained from condensing this important section. The section on squint, both paralytic and non paralytic is clearly written. Though only one page is allotted to the treatment of concomitant squint this is set out adequately and without bias.

We hope that in the next edition of the book more attention will be given to the field where ophthalmology overlaps general medicine. These sections fall below the standard of the remainder of the book notably in the chapter on diseases of the retina. The pages dealing with the retinal manifestations of vascular and renal disease lack precision and are out of touch with modern ideas. There is no reference to the important changes seen in the fundus in malignant hypertension. The section devoted to detachment of the retina could be enlarged with advantage to the general practitioner. The book is easy to read though the use of italics to emphasise a phrase or word in the middle of a sentence is excessive and distracts attention from the argument. The work as a whole owes much of its value to the excellence of its illustrations. The anatomical drawings and those which show the position of the two eyes in relation to one another are far in advance of those usually found in text books.

Surgical Pathology of the Thyroid Gland

By ARTHUR E. HERTZLER M.D. Surgeon to the
Agnes Hertzler Memorial Hospital, Halstead
Kansas and Professor of Surgery, University of
Kansas, London: J. B. Lippincott Co 1937
Pp 208. 21s

There seems round which this book is written is mentioned in the preface. If removing a part of a diseased gland is beneficial to the patient what is more logical than to assume that removing the whole will be better? The author suggests that all goitrous patients die a cardiac death even when the goitre is of the so called non toxic varieties and thus total thyroidectomy is the only logical treatment for a gland which is producing such a damaging secretion. He thrusts forward his views with an enthusiasm which is infectious making the reader wonder why he has ever committed the crime of partial thyroidectomy. On second thoughts however the lack of evidence is found in many places to detract from the value of the arguments. No figures are given in support of Prof Hertzler's belief either that patients with non toxic goitre die

a premature death or that total thyroidectomy is so rarely followed by symptoms of hypothyroidism. These views, which the author reiterates throughout the work, must not be allowed to supersede those held by the more orthodox. Prof. Hertzler adopts the classification of the American Society for the Study of Goiter dealing fully with the naked-eye and microscopic changes in each type. Each chapter is profusely illustrated by excellent microphotographs and concludes with a brief review of the literature. It is disappointing that nothing is said about the etiology of goitre in the chapter on general pathology. Very little space is devoted to chronic thyroiditis and carcinoma of the gland. The book is of very little value as a work of reference, but it makes pleasant and light reading and is excellently illustrated.

Buchanan's Manual of Anatomy including Embryology

Sixth edition By J. E. FRAZER D.Sc. F.R.C.S.
Professor of Anatomy, University of London
London: Baillière Tindall and Cox 1937
Pp 1772. 35s

The distinguished anatomist responsible for the new edition of Buchanan's Anatomy has assured to this notable text book a great future. He has combined the advantages of studying the body by regions with the systematic consideration of osteology, neurology and embryology and both cytology and microscopic anatomy are presented adequately. To accomplish all this nearly 1700 pages of text and 1042 illustrations have been required. A glossary of special anatomical terms and a serviceable index are additional attractions. Prof. Frazer has adopted the present English system of terminology which preserves some valuable traditional usages, is close enough to the International Latinised form to make it possible to pass easily from one to the other and is handy and simple.

Many of those charged with the care of medical education are concerned about the immense volume of information nowadays presented to the student. It is felt that few if any can assimilate and reproduce it all that the attempt to do so entails individual reflection, and that in this technical flood education and training have been overwhelmed. Though there are just grounds for apprehension things are not really so bad as this. Indeed amidst the gloomy forebodings of our time it is some comfort to dwell on the great advance in the education of the engineers of medical students to learn and the success with which they meet the demands made upon them. This text book of anatomy will be judged then by a standard which is concerned not with the volume of facts but rather with their wise selection the manner of their presentation and the interest and pleasure with which they are received. Judged by this standard this book should continue to increase in popularity with students. It is not proposed here to consider its features in detail some of them are regrettable—e.g. the omission presumably deliberate of radiology and—a small point—the relation illustrated of the artery striata to the posterior calcareine suture is unusual; but the embryology demands special mention. This is Prof. Frazer's special field. His numerous published researches are regarded highly by other embryologists and he has published a book on this

subject which contains the outcome of many years of fine work. In this text book of anatomy he has assembled and illustrated the processes of growth and differentiation, and his mastery of the subject makes this section a notable contribution.

Surgical Anatomy

Third edition By GRANT MASSIE, M B, M S Lond, F R C S Eng, Assistant Surgeon, Guy's Hospital, Lecturer in Operative Surgery, Guy's Hospital Medical School London J and A Churchill 1937 18s

WHY there should be a demand for books on surgical anatomy is one of the mysteries of medical education. The student who has spent at least eighteen months learning anatomy must have acquired the sort of familiarity with some book on anatomy which materially facilitates revision, while a practising surgeon nearly always finds, if he wants to refresh his knowledge of the anatomy of some operation, that for the detailed information he requires he has to consult an ordinary anatomical text book. It is clear, however, that a large number of students feel the need for a treatise on surgical anatomy and their need is here met in a very efficient way. The information is given in an attractive form, so that the reader's interest is likely to be maintained. There are very few omissions but there does not seem to be a description of an approach to the back of the knee joint nor of the anterior operation for excision of the stellate ganglion. The illustrations are good, many of them having been borrowed from reliable sources, and the diagrams clear

American Pharmaceutical Association Year Book

1934 Vol. XXIII Washington, D C American Pharmaceutical Association Pp 467

THOUGH published in 1936 this book reviews publications during the year 1934. Brief extracts of papers from over 80 journals are given and are classified under the main headings of pharmacy, materia medica, and chemistry. There is much of interest to the physician since many of the abstracts deal with therapeutics, and excellent author and subject indexes are provided. The volume contains many details of proprietary remedies which when collected from the international literature form an imposing array. A list of hormone preparations is given (p 87) and one can hardly help wondering if the ingenuity which is devoted to devising different names for the same substance might not be better employed.

How Animals Behave

By H G WELLS, JULIAN HUXLEY, and G P WELLS London Cassell and Co 1937 Pp 263 4s

THIS is a revised version of some sections of the "Science of Life" which the same authors published in one large volume some while ago. It is very cheap, in excellent format for convenient reading, and gives a most readable and interesting account of the behaviour of animals from protozoa to the apes, man's conduct is dealt with in another volume of the series. Apart from the exceptional clarity of the writing the book is easy to follow because it is a coherent tale of the evolution of behaviour and not a collection of curious anecdotes. The argument is that lower animals can learn by trial and error,

to which is later added heritable instinct which is more highly developed in, e.g., insects than in man, that constructive intelligence is found only in the apes and that generalised and abstract thought is the prerogative of man alone. It is unlikely that everyone will agree with this general outlook. Insects and birds do things which are very nearly intelligent. And if it is easy to make a bird look a fool by interfering with a natural train of instinctive reactions, it is equally possible that the right kind of poltergeist might have little difficulty in demonstrating the silliness of man. But we recommend those who are interested to read the book and with it, to get a rather different point of view, E S Russell's "Animal Behaviour" they can then form their own opinions.

Experimental Physiology

By GEORGE H BELL, M B, B Sc, Murrhead Lecturer in Physiology, University of Glasgow Glasgow John Smith and Son 1937 Pp 70 4s 6d

NEARLY all books giving instructions for practical exercises in physiology provide a description of the class exercises carried out and the advice given to students in a particular laboratory. This one contains nothing strikingly original, but tips on how to make class experiments work satisfactorily are always valuable to teachers. The experiments described here are on the frog and human subject, illustrations of typical results accompany many of them, and the alternate pages are blank for students' notes. The style is intimate and direct, but, as is inevitable, the equipment of the Glasgow laboratory is taken for granted. The book should be of great value to students of this school, but among others its circulation is likely to be limited.

Sex in Religion

By G SIMPSON MARR, M A, M B, Ch B, B.D., D Litt London George Allen and Unwin Pp 285 7s 6d

Dr Marr writes from the standpoint of a medical man who is also a churchman. That a balanced sex life is an important factor in health he shows in a series of historical chapters. These deal with primitive religions, the Old Testament, Egypt, Greece and Rome, the early and medieval church, the Reformation and modern times. His thesis is that though the Church has, up till now, adopted an ostrich like attitude to the problems of sex, it need not continue to do so. Dr Marr recommends that the churches of England and Scotland, working together should set up a commission to investigate what part they could play in imparting to children a proper knowledge of sex problems, in guiding adolescents through the most critical period of their lives, and in recognising the diverse factors which make for happy marriage.

The book is agreeably written and well documented—there is an appendix containing a list of 300 books which have been consulted. It says little that is new, some of the author's deductions, moreover, are of questionable validity—as for instance, that the increased use of contraceptives would go far to solve our unemployment problem. But though, to the medical reader Dr Marr may seem to be pushing an already widely open door, it must not be forgotten that clerical opinion on problems of sex is sometimes less realistic than medical, and tends to lag behind it.

THE LANCET

LONDON SATURDAY JUNE 19 1937

SECOND BEST CARE OF THE EYES

THE Northern Counties Association for the Blind has issued a warning against the indiscriminate sale of spectacles. The Association is not so far as we are aware dominated by registered medical practitioners. Its advice may therefore be listened to by the general public without any fear that it is an insidious attempt to bolster up a monopoly of professional practice. The Association expresses doubts of the wisdom of allowing a patient to select for himself a pair of spectacles from a tray on a street stall or in a multiple shop. The spectacles thus sold may be cheap and the properly prescribed spectacles obtained from an optician may be dear, but any reasonable or even generous expenditure on the care of the eyes and the preservation of the sight is justified. Local authorities have power under Section 66 of the Public Health Act of 1925 (to be replaced next October by Section 176 of the new Act of 1936) to make any desirable arrangements for assisting in the prevention of blindness and for treating local residents who suffer from disease or injury of the eyes. The Northern Counties Association suggests that this statutory power might well be exercised so as to enable the poorer members of the community to have the best appliances. What has evidently impressed the Association is the twofold danger that inexperienced selection from a tray may fail to correct defective vision and lead to the neglect of the disease underlying the defect. The insidious onset of chronic glaucoma for instance needs considerable skill to diagnose. Failure to secure skilled examination of the patient's eyes may mean that a fair chance of preventing blindness is thrown away. Voluntary agencies are doing what they can. In addition to the clinics and the free services of specialists in the great hospitals the National Ophthalmic Treatment Board enables anyone with an annual income of less than £250 to obtain examination of the eyes and the prescription of glasses by recognised ophthalmic medical practitioners at a much reduced fee. If the fee is still out of reach of the poor patient the local authority might make use of its power under Section 66. Blindness has become a special concern of the community. It is a false economy that leaves the layman to be his own expert. No one wants to overstate the danger. It is on record however that the departmental committee on the Optical Practitioners Bill of 1927 reported itself satisfied that the number of cases in which the patient might miss the opportunity of remedial treatment if the patient were not examined by an oculist was by no means negligible.

Just at this moment as it happens, the National Health Insurance Joint Committee has issued some amendments of the Additional Benefit Regulations of 1930 in relation to ophthalmic treatment and optical appliances. There is to be a new committee representing the approved societies and the opticians, to administer ophthalmic benefit. After next September an approved society may adopt a scale of charges drawn up by this committee for the provision of optical appliances of a defined standard, and in particular for allowing as a separate item 'any charge for services rendered by an optician whether an optical appliance is supplied or not.' Article 25 of the 1930 regulations defined the provision of optical appliances as including any service rendered by an optician incidental to the provision of the appliance. The recent amendment seems to contemplate that the optician shall perform the ophthalmic examination which in the 1930 regulations meant 'an examination of the eyes by a medical practitioner having special experience of ophthalmic work.' If by its new regulations the Ministry of Health is giving official recognition to a form of unqualified medical practice, it is a curiously unobtrusive method of reversing the conclusions of one Royal Commission and two departmental committees. The latest annual report of the National Ophthalmic Treatment Board dealt faithfully with those apologists for the sight-testing optician who claim that when glaucoma is present he 'may be considered absolutely capable in detecting the condition and thus safe from the public point of view. However admirable the education of opticians their work has been the correction of errors of refraction. Their curriculum is not designed to equip them with the knowledge of physiology and pathology needed to detect the beginnings of disease.'

The Minister of Health, in notifying the issue of the amending regulations announces that they were framed after consultation with members of the medical profession. It would be interesting to learn what those representatives told the Ministry and how far the Ministry paid attention. Are those whose sight is defective going to get the best service? In a recent letter to the *Times* Dr G. C. ANDERSON justifiably criticised the Ministry for encouraging the patient to seek what is admittedly the second best. Sir KINGSLEY WOOD is himself satisfied that the ultimate ideal is for all persons to go to medical eye specialists and his plea that the number of these is insufficient has been denied by Sir JOHN PARSONS. The new regulations seem to deserve longer consideration than they have received. Issued by a procedure based on the sometimes overworked allegation of departmental urgency they are technically Provisional Regulations. This should mean that, so far as England and Wales are concerned though the regulations take effect forthwith there will be an opportunity for any public body to object to them before they finally are published as Statutory Rules. The opportunity should not be neglected.

FRACTURE CLINICS

IN a number of hospitals throughout the country a special department has now been set up for the treatment of fractures and the practice is extending. The public health authorities are beginning to recognise the importance of these clinics and to be interested in their organisation as a matter of public benefit and public economy. For this reason, as we noted last week, the committee appointed last year by the Ministry of Health to inquire into the rehabilitation of persons injured by accidents has thought well to issue an interim report¹. The committee is anxious to ensure that the organisation of fracture clinics shall proceed along the right lines, so that individual clinics shall be efficient and established with due regard to local needs, while overlap is avoided. The report therefore deals with (1) the type of treatment and plan of clinic that should give the best results, and (2) the distribution of fracture services so as to put them in reach of all patients in towns and rural districts. The committee bases its scheme on the assumption that the clinics will be established at and as an integral part of existing hospitals. The principle is that all fracture cases shall be concentrated in one department and under a single control to ensure continuity of treatment and supervision of all stages of recovery right up to the re-establishment of full working capacity.

The type of fracture clinic planned by the committee has at its head a surgeon who is paid for his services. The prime responsibility is his and he is expected to devote a considerable proportion of his time to the work. The remuneration suggested is £500 for a surgeon-in-charge at a hospital of 500 to 1000 beds dealing with 2000 to 2500 fractures in the year, £300 where the hospital has 200 to 500 beds, with a proportionately smaller number of fracture cases. In the small hospitals, of 50 to 200 beds, the salary is proportionately reduced. For all the larger hospitals the scheme provides for one or two full-time assistants, who are senior members of the resident staff, for the services of a resident radiographer, and for clerical assistance. The efficient keeping of records is an essential part of the work. The services of two resident house surgeons, already on the staff of the hospital, are called on as required. For the small hospitals, the appointment of full-time assistants may not be justified, but arrangements would be made to secure the part-time service of the existing staff. It will be seen that this scheme departs in one main particular from the ordinary policy of voluntary hospitals in that it involves the payment for services of a member of the visiting staff. The committee points out that the time and service that will be required from the surgeon and the fact that knowledge of fracture treatment is of small financial advantage in private practice means that, without payment, hospitals cannot expect to secure the man best

qualified for the work. One paragraph of the report suggests the possibility of fracture clinics becoming part of a general accident service which would no doubt include the supervision of all extensive injuries of the soft parts and ensure the skilled treatment of tendon injuries. Under the purview of such a service would naturally come the equipment and training of the ambulance corps. In the future the accident work of hospitals is likely to be divided off more sharply from the treatment of sickness, from which it differs profoundly. It is not good for a patient with a fractured leg or arm to be treated side by side with ill patients, whether in wards or in out-patient clinics. He is not ill, and what he needs is healthy competition in recovery with other patients like himself. Malingering is rare in a fracture clinic.

The report cites four criteria of correct reduction of fractures: (1) the limb must be the right length, (2) the bone must be in correct line, (3) there must be no rotation or twisting, (4) joint surfaces must be correctly restored. Fixation by plaster of-Paris applied next to the skin is the general method advised. Traction is mentioned as the method of choice for fractured femurs. The importance of early use is emphasised as the basis of the modern treatment of fractures. In the planning of the routine work of the clinic arrangements are made for immediate treatment of casualties, for a session at which every case can be seen daily for the first few days, and for a weekly session at which attendance is arranged of all out-patient cases of fracture under treatment, all former in-patient cases of fracture, and cases reporting at varying intervals for follow up purposes. This clinic is conducted by the surgeon in charge. It is strongly recommended that special wards be provided for fracture cases which require admission, and that they shall be placed under the care of the surgeon in charge of the clinic. Special arrangements may be made for fractures of the pelvis and for head injuries, and also for cases in which the fracture is a complication of an abdominal injury. That the equipment of the department need not be very expensive was shown by the report we recently published² of the municipal accident service at Cardiff. The covering letter sent with the report to the county councils and county borough councils expresses the hope that if these bodies are intending to establish clinics for themselves they will refer to the detailed scheme given in the appendix. Evidently the Ministry of Health expects local authorities to shoulder the responsibility for the efficient treatment of accidents. Suggestions are made for the treatment of patients in outlying districts by cooperation between small cottage hospitals and larger centres. The establishment of accident services is in many cases held up by lack of money. Last October a conference on the treatment of accidents was held in Manchester by the General Federation of Trade Unions. Employers' organisations are also showing interest in the efficient treatment of their workers. Could these bodies

¹ Interim Report of the Inter Departmental Committee on the Rehabilitation of Persons Injured by Accidents. H.M. Stationery Office. Pp. 20. 4d.

² *Lancet*, Jan. 9th, 1937, p. 107.

not induce the great insurance companies to contribute? It is they who stand to gain most by the quick and complete recovery of the injured person. The numbers concerned are large. At 825 hospitals (724 voluntary and 101 municipal) which replied to the committee's inquiries nearly 202,000 new fracture cases were treated in the year 1935.

SUPERANNUATION IN THE LOCAL GOVERNMENT SERVICE

THE fact that local authorities are not obliged to make provision for their retired employees though most of them including the more important ones have made such provision has long been a matter of discontent. The Local Government and Other Officers Superannuation Act 1922 has been adopted according to Sir KINGSLEY WOOD by nearly 950 local authorities and some 25 have Local Act schemes but 587 authorities have made no arrangements for superannuation. It is not only to protect the employees of the last group but to encourage free migration throughout the country in a service where varied experience is of high value to senior administrative officers that an extension of superannuation provision is urgently needed. Hitherto, again even those local authorities which have made such provision have been free to decide which of the posts in their service are designated as established and only the employees occupying established posts are superannuable. A Bill now introduced¹ is designed to ensure this privilege for all whole time officers as regards part-time officers and servants there is no compulsion their inclusion in the scheme being left to the discretion of the authority. The normal age of retirement will remain at 65 except for female nurses midwives and health visitors who will retire at 60 or if they wish at 55 provided they have then completed 30 years of service. This permissive clause brings the scheme to some extent into line with the Federated Superannuation Scheme for Nurses and Hospital Officers adopted by most of the voluntary hospitals of the country which makes 55 the age of retirement but a more fundamental difference unfortunately remains which will complicate any attempt in the future to follow up the co-ordination of the superannuation practice of local authorities by linking it with that of the voluntary institutions. The difference is that whereas under the Federated Superannuation Scheme the employer pays annually double the contribution of the employee (10 per cent. and 5 per cent. respectively) the local authority pay only the same proportion of the remuneration as do their officers and servants. Hitherto this has been 5 per cent. but the Bill proposes that in view of the change in interest rates since 1922 when Parliament last dealt with the matter the contribution in respect of officers shall in the future be 6 per cent. from either party. The Bill in its present form offers only one small concession to those officers who may wish to seek experience in

institutions other than those under local authorities 12 months is substituted for 6 as the period constituting a disqualifying break of service. Migration between the services of all local authorities throughout the country, however which was formerly liable to be penalised by loss or grave diminution of superannuation prospects will involve no handicap if this Bill becomes law. Reciprocal arrangements are now for the first time introduced between authorities such as the London County Council which have local Acts and not only between those which have adopted the Act of 1922 and this applies to transfer values as well as to the reckoning of previous service. A criticism made of the Bill at its second reading concerned the fact that the inclusion of servants in the superannuation scheme remains optional and Captain ELISTON expressed disappointment that no provision was made in the Bill for the optional addition of a number of years not exceeding ten to those which professional officers had actively served. His plea for special consideration of the position of medical officers in view of the late entry into the service due to long undergraduate and post-graduate training was a cogent one. The debate recorded on another page was clearly only the first skirmishing round on a complicated issue.² The relief that legislation has at last been introduced on the lines recommended by the departmental committee under Sir ARTHUR SELBY BAKER as long ago as 1928 will not prevent a careful scrutiny of the provisions of a Bill which will affect an increasing number of medical officers nurses midwives health visitors and other employees as the service of local authorities expands.

ANTIBODIES AGAINST HORMONES

A NEW and fertile field of research was thrown open when COLLIP and ANDERSON proved that animals can develop resistance to hormones administered to them over long periods.³ It has been established that the thyrotropic and gonadotropic hormones of the pituitary evoke such a resistance and it is reported that the growth and ketogenic factors of the pituitary also do so. Clinically this observation is important first because it may explain why patients become refractory to further treatment and, secondly because an antagonistic substance produced in animals might be used to relieve disorders caused by excess of hormone. That such a substance can exist is shown by the fact that the serum of resistant animals will inhibit the action of the hormone in other animals whether this hormone is secreted by the animal or injected by the investigator.

The hormones known to call forth this resistance to themselves are protein like bodies and it has been suggested that like many proteins they act as antigens provoking an immunity due to the formation of antibodies. Clearly there is an analogy at least between the well known mechanism

¹ Bill 141. H. M. Stationery Office. 1s.

² A memorandum (Cmd. 442) explaining the Bill has been issued and can be obtained from H. M. Stationery Office. 2d.
Collip J. D., and Anderson L. St. *Lancet* 1934 i 74, 761.

of acquiring immunity to proteins and the formation of protective substances against hormones, and it is credibly reported that the intensity of precipitin reactions and complement-fixation reactions run parallel to the protective properties of the sera in the animal. One difficulty has been to distinguish between reactions due to hormones and those due merely to specific proteins. It has, however, been shown that if antiserum to ox pituitary is precipitated with ox serum, the supernatant liquid contains protective factors against ox pituitary, and this rules out the possibility of the antigenicity being bound up with the specific proteins. On the other hand, there is no known mechanism of auto immunisation by which an animal becomes immune to its own pituitary, the hormone, to produce an antiserum, must come from a different species. This implies generally, in the present state of pituitary hormone chemistry, that it must contain heterologous protein, but it would appear that a greater zoological difference between the species from which the extract is made and the species which receives the injections is necessary for the formation of antisera to hormones than for the formation of antisera to serum proteins. The activity of hormone antisera against hormones is, again, subject to species- and source specificity, for antiserum to gonadotropic hormone from pregnant-mare serum is only partially effective against other forms of gonadotropic hormone, and antiserum to extract of human pregnancy urine is not effective against ordinary pituitary extracts, whilst antiserum to ox pituitary is only partially effective against extract of human pregnancy urine. The immunological phenomena are consistent with the existence of gonadotropic hormones that differ in each species of animal but have less intricate and distinctive patterns, and structures less differentiated from species to species, than the serum proteins. Alternatively, the same gonadotropic hormones may serve a group of related species. The hormonal activity may be conceived as due to a prosthetic group common to all species, but so far it has not proved possible to separate a simple active compound containing such a group, in the way that thyroxine has been separated from thyroglobulins. The determinant groups responsible for serological reactions must, however, be independent of the hormonal prosthetic group, for antisera to gonadotropic hormone may be prepared with extracts of pregnancy urine whose potency has been lost after storage, or even from a fraction from normal male urine having negligible hormone activity. Logical as the scheme may seem, it may not be the whole story, and various considerations remain to be taken into account, especially in the case of the thyrotropic hormone. Dr A. LOESER, whose work carries great weight, dealt with some of these in the discussion reported on p. 1462. His most striking discovery is that antithyrotropic activity is present in normal sheep's serum, and it is claimed that this activity can be concentrated into a particular fraction. Confirmation of these results would lead to modification of the straightforward immunological concept according to which an animal

does not form antibodies to its own protein like hormone.

Another provocative contribution to these problems is made by Prof JULIUS BAUER and his collaborators in Vienna,⁴ who find that injection of thyroxine into rabbits produces a resistant state, as judged by the disappearance of the fall in serum-lipase and of the loss in weight which are regarded as typical thyroxine effects. When this resistant state is reached, the serum shows a positive complement-fixation reaction if thyroxine is used as antigen. Normal rabbit serum does not give this reaction. When the sera of human patients are examined, it is found that this complement-fixation reaction with thyroxine is given by a large proportion of those with hyperthyroidism whereas the sera of those with other diseases are usually negative. Operation on hyperthyroid patients followed by cure is accompanied by a disappearance of the thyroxine complement-fixation reaction. These observations are potentially of great clinical importance and of theoretical interest in that they suggest that resistance to thyroxine is bound up in some way with a mechanism that is on the borderline of recognised immunological reactions. A full immunological effect thus cannot be, for the sera of thyroxine-resistant rabbits does not confer resistance on normal animals. This work has been extended to the demonstration that not only thyroxine but also diiodotyrosine, adrenaline, sympatol, insulin, tyrosine, and phenol can act as antigens, the suggestion being that the phenol group is the centre of a group of more or less unspecific serological reactions. More definite conceptions of these reactions must await further study. The complement-fixation reaction itself is little understood, and both immunology and endocrinology stand to gain from closer examination of these resistance phenomena.

THE MODERN MENTAL HOSPITAL

IN opening the new Runwell Mental Hospital (briefly described on p. 1487) Sir Kingsley Wood, the Minister of Health said that the national outlook towards mental disease had in recent years completely changed, and in no branch of public health services had there been such striking improvements in methods of treatment. The provision in the Mental Treatment Act of 1930 whereby voluntary patients could be admitted to public mental hospitals, had already had remarkable results. Of the 25,000 patients admitted to such hospitals last year nearly 27 per cent were received on a voluntary footing. He did not think there was proof that the incidence of mental disorders in this country was rising. Nevertheless the problem was a considerable one and there were some 150,000 persons in this country at present under care by virtue of the Acts providing for Mental Treatment, whilst there were of course many more who suffered from mental instability and nervous disorders. Probably something like a third of all sickness apparently physical, was in fact nervous in origin. He was glad to say that increasing numbers were voluntarily seeking treatment in the early stages of the disease and while they were still able to coöperate with the doctors.

ANNOTATIONS

STATISTICAL TACT

THIS week we publish in the form of a slender book¹ of under 200 pages Dr Bradford Hill's pithy articles on the application of statistical principles to medical investigations. Those who followed these articles in the pages of THE LANCET in the early months of this year will find in the book some useful practical additions—notably a set of simple definitions of commonly used statistical terms and standard errors—a note of the precise meaning of certain expressions sometimes loosely used and the conventions which are usually followed in expressing certain rates—e.g. maternal mortality rate, attack or incidence-rate fertility rate. There is included also by permission of Prof R A Fisher F.R.S. and Messrs. Oliver and Boyd a table constructed by him which is particularly useful for testing the presence or absence of association between characteristics which like so many characteristics in medical work, cannot be quantitatively expressed.

Dr Bradford Hill in his preface repudiates with some warmth any suggestion that the statistician is a cold blooded organism who enjoys either refuting other workers' conclusions or explaining that though these may well be true valid evidence of their truth is sadly lacking. He does not fancy himself in the rôle either of the armchair critic or of the confirmed sceptic, and he resents being forced into the ungracious position of having to turn down as inconclusive another man's sincere and serious work. The proper solution is for the worker in medical problems clinical as well as preventive himself to learn something of statistical technique both in experimental arrangement and in the interpretation of figures. Dr Bradford Hill has shown that contrary to the general idea no special mathematical ability is needed to grasp and apply elementary statistical principles and he has certainly illustrated precept by example. These examples make it clear that it is not only the senior worker surveying case notes collected over a long period with a view to extracting their statistical message who will find here the help he needs. Whoever is writing an article preparing a university thesis planning a series of experiments, contemplating the issue of a questionnaire or concerned with deductions from samples typical (he hopes) of a larger population will gain from its study and most of all perhaps the doctor anxious to use the opportunities of general practice to solve some clinical or epidemiological problem.

The main lessons the book teaches is that it is before an investigation is started rather than after it is completed that the principles underlying the collecting and interpreting of numerical evidence should be grasped and that far from being a trivial and time-wasting ingenuity the application of the numerical method to the subject matter of medicine is an important stage in its development.

THE DRUG TRAFFIC IN EGYPT

THE report of the Narcotics Intelligence Bureau² to the Egyptian Government for 1936 if less dramatic than the seven previous annual reports yet affords

invaluable evidence of successful vigilance in dealing with illicit traffic in noxious drugs. T W Russell Pasha, the active director of the Bureau claims that Egypt has for years had more drastic legislation against illicit traffic than such as is provided for by the last convention on the subject drawn up at Geneva. While the general situation in Egypt is now said to be fair to medium it is claimed that a vast improvement has been effected since 1930 and the number of convicted traffickers and convicted addicts continues to fall. Indeed under the post treaty régime the possibility of an almost drugless Egypt is foreseen by the indefatigable Pasha. Internationally however the picture is not so reassuring. The situation at Suez is disturbing. It is reported that the majority of the Manchukuo heroin destined for America is now being routed from the Far East ports through the Suez Canal. Commerce in opium and heroin in Manchukuo appears to be entirely uncontrolled. The world source of illicit white drugs to day is China north of the wall and for some distance south of it. These areas are either under direct or indirect Japanese control. The chief market for this Chinese heroin is said to be America, no longer via the Pacific to Western ports, but through the Suez Canal to European ports for trans-shipment to New York. According to Russell

Ships personnel and passengers can buy a kilo of heroin in Tientsin for 6000 francs at Suez and Port Said they can find ready purchasers at 12 000 francs for the kilo who will dispose of their goods eventually with a very big profit to themselves.

The report concludes by urging the closest possible co-operation with Great Britain and the United States so that the good work done by the League of Nations shall not be undone and the world re-poisoned solely and entirely for the monetary profit of a mob of international rascals living under the protection of the political chaos of the Far East."

SECOND INTERNATIONAL CONGRESS FOR MICROBIOLOGY

So many and so diverse were the subjects under discussion at the meeting of the International Congress for Microbiology held in London during July of last year³ that even the final issue of the papers could only be given in the form of abstracts. The report of the congress has now reached us in book form⁴ under the editorship of Dr R St John Brooks the honorary general secretary of the congress. Microbiologists throughout the world will find the volume full of interest and instruction as much of the work was chosen for presentation on the grounds that a clear international understanding of it was desirable. The discussions range through all the branches of parasitological and economic microbiology but no doubt as with all really live meetings the most important part of the transactions were in the personal conversation and demonstrations which took place during the congress. Among the questions of medical interest discussed were filtrable viruses, malaria, the diagnosis of enteric fevers, the prophylaxis of diphtheria and whooping-cough and the serum treatment of diphtheria, staphylococcal pneumonia and meningococcal infections, enteric fever and so forth. The communications on the practical

¹ Principles of Medical Statistics. By A. Bradford Hill. M.D., Reader in Epidemiology and Vital Statistics in the University of London (London School of Hygiene and Tropical Medicine). Fellow and Member of Council of the Royal Statistical Society. London: The Lancet Ltd. 1937. Pp. 192. 6s.

² Egyptian Government, Central Narcotics Intelligence Bureau. Annual report for the year 1936. Govt. Press, Kulliyah, Cairo, 1937.

³ Lancet 1936 2, 276 and 331.
⁴ Second International Congress for Microbiology. London 1936. Report of Proceedings. Edited for the executive committee by Dr R. St. John Brooks (honorary general secretary). London, 1937. pp. 679.

subjects give a good idea of present methods and tendencies in immunological forms of treatment. Prontosil and its congeners in the treatment of streptococcal infection came under review. Other sections covered microbiology in relationship to dairying and water supplies, ensilage production, the destruction and preservation of timber, problems of the fermentation and canning industries also received attention. From such a wide selection it is almost invidious to select any special subject as of outstanding interest, but in the account of advances in virus study one reads with something of a shock the announcement of Prof. A. R. Dochez that he and his colleagues have kept the viruses of influenza and common cold alive and infectious for as long as a year in chick embryo medium. The novelty has not yet worn off the experience of watching filtrable viruses emerge from being mysterious and impalpable "qualities" to reach their present status as cultivable microorganisms, with a defined morphology and a complicated and polymorphic life history. All classes of microbiologists will be interested too in the discussions on the methods of maintaining the viability and virulence of bacteria, on selective bacteriostasis, the preservation of immune sera, the chemistry of antigens, and the chemical activities of microorganisms. Among matters of more popular interest were the investigations recorded by Mr. B. E. Proctor of Cambridge, Mass., on the microbiology of the upper air. With the aid of an apparatus which he calls the bio-aerocollector, successive samples of air can be collected by aeroplane and submitted to microbiological examination. Viable bacteria, moulds, and yeasts were found to be present at altitudes of 20,000 feet or more during all seasons of the year and even pollen grains could be collected at very high altitudes. The volume will appeal to readers who wish to gain some idea of current activities in the world of microbiological research.

DR JEKYLL DIAGNOSES MR HYDE

THIS was Sir Walter Langdon Brown's witty title for his Cavendish lecture to the West London Medico-Chirurgical Society on June 3rd. He began by saying that to the inheritors of nineteenth-century materialistic medicine it was not a welcome discovery that the psyche was a causal factor in disease. The Freudian attitude to the unconscious was perhaps apt to give it too dark and depressing an impression. He himself started, therefore, from a biological standpoint as Rivers would have done. Structurally numerous vestiges of earlier evolutionary phases were to be recognised in the human body, and the human psyche from this point of view was likewise a product of evolution which showed many archaic features. Rivers did not accept Freud's conception of a censorship; he regarded the fantastic and symbolic forms in which hysteria and dreams manifested themselves as a regression to a lower level which was natural to the infantile stages of human development, individual or collective. We reached the higher levels of our nervous system on the stepping-stones not only of our dead selves but of our long dead ancestors. The lecturer could not doubt that medicine would have to become increasingly psychological in its approach. The new psychology was a compromise, a selection from the doctrines of different schools, but it was the needs of the present time that had led to its development. If some academic psychologist scoffed at it the simple reply could be made that it worked. Although it was only in its infancy

its influence was overflowing beyond the confines of medicine into many other fields of thought, just as did Darwin's exposition of the principle of evolution. A compact body of well-informed medical opinion on the subject could be a much needed educative influence in a world which seemed to be steadily growing more psychologically sick. At the present time, added Sir Walter Langdon Brown, the darker side of the collective unconscious was assuming a volcanic energy. If it was not to prevail we must live up to the Greek maxim, "Know thyself," or Caliban would reconquer the island he inherited from Sycorax his mother. "Dr. Jekyll must diagnose Mr. Hyde by recognising his origin. Am I too optimistic in hoping that the profession to which Jekyll belonged can by psychological insight play an important part in leading the way to a calmer, humaner, and more rational world?"

SOYA BEAN OR SKIM-MILK FOR INDIA?

THE difficulty of securing proper nutrition for the people of Europe seems great enough, but it shrinks into insignificance compared with the difficulty of securing proper nutrition for the people of India. The nutritional laboratory of the Indian Research Fund Association at Coonoor was already busy with practical problems when it was directed by Sir Robert McCarrison, and its fine traditions are being carried on by Dr. W. R. Aykroyd (who passed straight to it from the Health Section of the League of Nations) and his Indian colleagues. One of the many questions tackled is what foodstuffs, of those available, can best be used to supplement inadequate Indian diets, and a fruitful inquiry of this sort has just been reported.¹ Two methods of investigation were followed. One method was to weigh and measure groups of suitable children of whom some received the supplements to be tested while others acted as controls, and the second method was to reproduce as exactly as possible the supplemented and unsupplemented diets and to compare the growth rate of rats receiving these. Excellent co-operation was obtained from missionary hostels for children where the diet was similar to, but rather better than, that consumed by the children at home. The supplements chosen were 1 oz. of dried (equal to 8 oz. liquid) skim milk daily, or 1½ oz. of soya bean daily. The result was very striking, and was confirmed by the animal experiments. There was an impressive increase in weight and height among the children receiving skim milk, compared with the negative controls, but no benefit to those receiving soya bean. An improvement in general condition, a lessened liability to illness, and an increased vitality were also conspicuous. The outcome of the test is surprising, because cultivation of the soya bean has been advocated as being perhaps the key to the nutritional problem of India. Certainly the supply of protein of good biological value in such diets as those under consideration, described as "poor Madrassi" or "poor Hindu," is low, and one would have expected that the comparatively good protein of the soya bean would have gone some way to remedy it. It is of course possible that it did do so, but that the coexistence of some second grave deficiency in the diet was a limiting factor which prevented the benefit from appearing. If the skim milk provided both the good protein and the other limiting factor a double benefit would appear. Aykroyd and Krishnan suggest that this second factor supplied by the skim

¹ Aykroyd, W. R. and Krishnan, B. G. *Indian J. med. Res.* 1937, 24: 1093.

milk and not by the soya bean is some constituent of the vitamin B₁ complex. A great problem of national housekeeping in many European countries is the disposal of a vast surplus of skim milk. India could use this if it were dried and Aykroyd and Krishnan discuss the practical politics of this suggestion. To-day they find, dried skim milk imported into India is too expensive to be used by the people but not enormously too expensive. It is subject to a 30 per cent import duty and if this impost could be abolished the cost would no longer be prohibitive and a big step would have been taken towards rescuing the children of South India from "a poor" state of nutrition, with their physical potentialities largely undeveloped.

BENZEDRINE

THE many and curious effects of benzedrine which remained unnoticed for twenty years after Barger and Dale described it in 1910 continue to attract the attention of investigators both of the dilettante variety who take a dose or two of the drug out of curiosity or under the stress of approaching examinations and of the more serious kind who write papers about it. An annotation in these columns¹ last year drew attention to its main effects—namely a rise in blood pressure, a relaxation of gastrointestinal spasm and a striking mental change involving euphoria, loss of fatigue heightened intellectual activity and talkativeness. Since then Davidoff and Reifenstein² have reported the effects of a 10-14 days course of benzedrine on normal subjects and on several groups of psychotic patients. The manifestations observed, both subjectively and objectively are extraordinarily numerous and varied. It is abundantly clear that benzedrine acts very differently on different people. In the ten normal subjects, elevation of mood over talkativeness and an increase in motor activity and general efficiency were the most frequent changes. If fatigue had been present it disappeared. But five of the ten developed a state of irritable restlessness which they did not relish and from the case reports we learn that the increase of activity and efficiency sometimes involved a dangerous degree of disrespectfulness to superior officers on telephones. Fatigue sometimes appeared in subjects who had not felt it before taking the drug. A host of minor bodily sensations pleasant and otherwise are mentioned. In a number of the subjects all effects diminished after the first few days, and little abnormality was observed in the second half of the period of administration. The action of the drug in the psychotic patients many of them in depressed states was roughly similar in kind but less in degree and there was the same great variability. A detailed analysis led to the tentative conclusion that more stimulation occurred in patients depressed from toxic or organic causes (such as alcoholism) than in those with purely psychogenic disorders and to the suggestion that the drug may be of value in making the minds of depressed or self-absorbed patients more accessible to investigation or psychotherapy. No use for it comparable to that in narcolepsy has emerged. On the other hand Solomon Mitchell and Prinzmetal³ have produced a fair case for its beneficial effect in post-encephalitic parkinsonism. They treated 29 patients some with benzedrine alone and some with benze-

drine and hyoscine or stramonium. Nearly all of them experienced a decrease in drowsiness, when this had been present and an increase in energy and well being which was therapeutically well worth while. No clear effect on rigidity or tremor could be demonstrated but—most strikingly—six patients who suffered from oculogyric crises lost this distressing symptom completely and two others almost completely under the influence of benzedrine. Since inhibition of sleep is the conspicuous central effect of benzedrine this observation accords prettily with Sir Arthur Hall's thesis⁴ that oculogyric crises are really episodes of partial and disintegrated sleep. Solomon and his colleagues found by contrast that the drug was of no use in arterio-sclerotic parkinsonism or in psychotic patients with conspicuous asthenia and out of their large experience they join other authors in giving warnings against its indiscriminate use. Its action varies so much and the effects of its repeated use are still so little known that caution is clearly advisable, especially in its administration to normal or relatively normal people as distinct from those with chronic and incurable disorders.

CORRELATION BETWEEN INTELLIGENCE AND SIZE OF FAMILY

AN investigation into the correlation between size of family and intelligence was recently undertaken⁵ by Mr R B Cattell Ph.D. with a subsidy from the Eugenics Society. Specially designed non-verbal intelligence tests were applied to two groups of children of ten years of age who went to school in the urban area of Leicester and a rural area comprising the villages to the north and south of Dartmoor. The urban group comprised 2873 children and the rural 861. Briefly Dr Cattell found that the stupider the children the larger were their sibs. In the urban area the mean number of children per family was 3.36 in the rural 3.03. The urban children of an intelligence quotient of 170 belonged to families wherein there were on average 2.36 children those with a quotient of 70 to families whose average size was 4.13. Comparable figures for the rural children were 1.80 and 4.21. Children with quotients between these extremes belonged to families whose size was roughly in inverse proportion to their intelligence. Dr Cattell draws from this data the conclusion that our national intelligence being very largely hereditary is declining at the rate of about three points in a generation or a point a decade. In a foreword he asks that his results and conclusions be submitted as early as possible for confirmation to a competent commission of social psychologists and economists and that if confirmed they should be taken into account by the Ministry of Health and the Board of Education.

The facts adduced by Dr Cattell are unquestionably interesting and suggestive but the informed reader will feel that they hardly support the crushing superstructure of social and philo-sophical theories which is built on them. The technical basis of the inquiry receives but the scantiest discussion. No details are given of the specially designed non-verbal intelligence tests which were employed; the reader is not told whether group tests were used and the all-important question of sampling is dismissed in a footnote. The confident quality of the generalisations and the boldness of the

¹ *Lancet* 1936 2, 11. ² *J Amer med Ass* May 27, 1937, 103. ³ *Id.* 1937, 103. ⁴ *Id.* 1937, 103. ⁵ *Id.* 1937, 103.

⁴ *Id.* 1937, 103. ⁵ *Id.* 1937, 103. ⁶ *Id.* 1937, 103. ⁷ *Id.* 1937, 103. ⁸ *Id.* 1937, 103. ⁹ *Id.* 1937, 103. ¹⁰ *Id.* 1937, 103.

recommendations might even have been excessive if they had been based on hundreds of thousands of cases drawn from every county in England. Dr Cattell deduces from his figures that a real deterioration of our race is going on here and now, day by day, hour by hour. To increase the medical and social services of to-day, without at the same time demanding restriction of births by those who use them is, we are told, as damnable a piece of wickedness as has ever been condemned by moral law. The husband should, indeed, be imprisoned for bringing into the world children beyond his means and, in all probability, below average intelligence. In discussing remedies, military similes are used. The presence of deterioration, having now been clearly proved, can be attacked. In this generation, the fight has been launched; the fight is on, and will be won by men and women fit for the hand to hand fighting of committees, with stamina to carry the struggle into the dust and heat of social welfare work in sordid cities, and with courage to face what may at first be a withering fire from strongly entrenched ignorance and sloth. Dr Cattell's book suffers from language such as this:

SULPHANILAMIDE

EVIDENCE that *p* aminobenzenesulphonamide (= sulphani-*l*amide) protects mice against meningococci¹ has led to its trial not only in meningococcal² but also in gonococcal infections. R. M. Fry and also Buttle and his colleagues have found that it is as effective against small numbers of gonococci as it is against meningococci in broth medium *in vitro*, and although therapeutic tests on animals cannot be carried out with the gonococcus the experimental evidence seems to justify its further trial in this infection. Dees and Colston³ of the Johns Hopkins Hospital, Baltimore, report that since February of this year they have used sulphani-*l*amide in 47 cases of gonococcal infection of the genito-urinary tract. In 36 of these the gonococci and the urethral discharge disappeared in less than five days, and in only 3 was there no demonstrable response. "The most striking feature of our experience," they write, "has been that in no instance has there been a progression of the infection, even in cases which showed no response to treatment." It is not stated how many of the patients returned for examination, but in only 3 of those who did so was there any recurrence, and these were all men who had discontinued treatment after a prompt response. Some patients tolerated a daily dose of 1 gramme per 20 lb of body-weight for as long as a month without serious ill effects, but dizziness and lassitude were some times noticed at first, and sulphæmoglobinæmia was recognised in 1 of the first 19 cases (the remainder are not fully reported). It is not surprising therefore that Dees and Colston sound an "emphatic warning" about the possibility of unpleasant reactions, and though they are profoundly impressed by the prompt response, and especially by the way in which the spread of infection was checked—their object in presenting a report at this stage is to stimulate the careful use of sulphani-*l*amide in cases where large numbers of gonococcal infections can be closely studied. Such tests are already in progress in England, but we understand that the results so far obtained are less encouraging than those of Dees and Colston.

The latest paper by Rosenthal and his colleagues of the United States Public Health Service⁴ describes further observations on sulphani-*l*amide and related compounds in experimental pneumococcus, streptococcus, and meningococcus infections. These workers have prepared a new compound, disulphani-*l*amide, which on subcutaneous administration (but not by mouth) proved slightly more effective than sulphani-*l*amide against streptococcal infections in mice, though its "acute toxicity" was only one fifth that of sulphani-*l*amide. It was also more effective against meningococcal infections of mice. In this country Gray et al.⁵ have also prepared disulphani-*l*amide and report that (when given by mouth) it is slightly more effective than sulphani-*l*amide against streptococcal infection of mice, while its toxicity is half that of the sulphani-*l*amide by this route. The formula of disulphani-*l*amide is

and it is interesting to compare its effect with that of diaminosulphone as described by Dr Buttle and his colleagues.⁶

In the streptococcal infections of mice diaminosulphone proved 25 times as toxic as sulphani-*l*amide but 100 times as effective.

ARTIFICIAL HANDS THAT WORK

Baron Larrey relates in his memoirs that after the battle of Brezina he lay in bed, too exhausted to sleep, for on that day he had done more than 200 amputations, and as he lay there the thought came to him that it should be possible to use the muscles of the stump to provide motive power for an artificial limb. Some ninety years later Vanghetti, an Italian physiologist, made the first experiments on these lines, but the idea did not find practical application until the late war, first in Italy and then on a larger scale in Germany. V. Putti described some of these knee plastic operations at the Royal Society of Medicine in 1918,⁷ and in 1923 came a brilliant monograph from Sauerbruch of Berlin.⁸ First, a tunnel lined with skin is made through the triceps behind and another through the biceps in front. (If the amputation has been below the elbow joint, then the tunnels are made in the extensor group of muscles behind and in the flexor group in front.) When healing is complete each tunnel is traversed by a removable ivory peg from each end of which a string passes to the artificial limb. The hand itself has four fingers acting as one unit, and the thumb acting as a second unit, and movement of the units is effected by contraction of the flexor or extensor muscles of the arm. At the end of his Macewen memorial lecture delivered in the University of Glasgow last week Prof Sauerbruch showed a film illustrating the remarkable activities possible for patients who had lost both arms, several of the patients shown were in good employment as telephonists. The film opened with a view of two men fitting their own limbs without assistance. One of them then dressed himself, being able to carry out the finer movements necessary to button up trousers and coat. Another man, wearing his artificial hands, emptied a box of matches on a table and then with

fine dissecting forceps picked up each individual match and replaced it in the correct position in the box. The film next showed an exhibition of writing by two patients, one of whom had also lost an eye. Another two patients made a combined demonstration in which one entered carrying a pail of water which he poured into the empty pail carried by his colleague. This manoeuvre completed they offered each other cigarettes and lit up in the usual way. Finally there was a close-up of two artificial hands in action, a shot which had æsthetic as well as technical value.

THE FERMENTATION OF PASTEUR AND CLAUDE BERNARD

It is perhaps some consolation for ordinary men to behold great ones occupied by little quarrels. Generally speaking the great figures in the history of science have afforded fewer opportunities for us to reap this kind of consolation than have those who were great in literature and in the arts. Lawyers too, and certainly politicians, provide more frequent and more violent exhibitions of invective called out by trivial causes than do the leaders of science. These considerations heighten the interest of the story which Dr J. M. D. Olmsted relates¹ under the title *Claude Bernard's attack on Pasteur*. The title is a little misleading for the attack is to be found in notes which Bernard had never published and in all probability never intended to publish at any rate in the form in which they were found. The two men were close friends in their lifetime, Bernard being some nine years older than Pasteur whose career he actively encouraged. Pasteur it was however who was instrumental in gaining much needed improvements in facilities for scientific work in Paris and it was through his polemics that the Emperor was interested and that a suitable laboratory was provided for Bernard. The two scientists were as it well known both interested in the phenomena of fermentation and engaged in experiments to find out its nature and causation and to demolish the theory of spontaneous generation. Their attitude to the question was, however, not the same. Bernard believed that the process of fermentation was purely a physico-chemical one while Pasteur maintained that it was a form of life and did not occur without the presence of some living organism however minute. Bernard had actually helped Pasteur to demonstrate the truth of his contention by supplying the blood of a dog which Pasteur sealed in clean glass vessels and kept in an oven at 30° C. for six weeks. At the end of this time Pasteur was able to demonstrate to the Academy of Sciences that even blood would not ferment out of contact with germ laden air. Bernard nevertheless continued his own experiments, hoping always to be able to demonstrate the presence of some soluble ferment which caused the phenomenon of fermentation without the necessary presence of any living thing. Notes describing these experiments and the conclusions at which he was arriving contrary to those of Pasteur were the cause of the quarrel which arose after Bernard's death. Dr Aronval, Bernard's pupil and disciple who had been given the task of going through his dead master's papers took certain notes, with Paul Bert and Daubre to Berthelot. They appeared soon after in the *Revue Scientifique* with a preface by Berthelot, who had previously attacked Pasteur on the subject of fermentation. The fat was in the fire. How Pasteur found in the notes contradiction of the facts and conclusions which he had presented before the Academy and

absolute condemnation without any restriction of my views on fermentation in general and on alcoholic fermentation in particular how he did not believe at first that the notes were genuinely those of the dead Bernard and how he triumphantly produced new and convincing evidence in support of his own view should be read in Dr Olmsted's lively account. In a sense both the great men were right. Fermentation is a physico-chemical process as Bernard maintained, and its cause is an enzyme which is provided by a living organism as Pasteur asserted. Moreover at present no one has succeeded in producing the enzyme synthetically without the aid of living cells.

THE PAGET TRADITION

EVERY year the Research Defence Society commemorates its founder and first secretary by a lecture delivered at the annual meeting. On Tuesday last Prof. Grey Turner was the lecturer and in speaking on the debt of research to the Paget tradition he paid tribute to both father and son. Stephen Paget owed his belief in experiment and his real for science to his upbringing in the home of one of the leaders of medicine—an untiring worker who combined every day clinical practice with careful measurement, observation and collection of facts; a surgeon steeped in the history of surgery who knew what experiment had done for his art. Sir James Paget's idea of the doctor's aim is reflected in his presidential address to the International Congress of Medicine of 1881. We had better not compete where wealth is the highest evidence of success; we can compete with the world in the nobler ambition of being counted among the learned and good who strive to make the future better and happier than the past. And again in an address in 1863 to students at Bart's: That which will most harass you in your practice will be the apparent success of dishonesty. You must be prepared for it for it will not cease in your time if indeed it ever does. To Stephen Paget his father's biographer James Paget was a continuing inspiration and as Prof. Grey Turner said the most valuable of all the father's work for the promotion of research was the stimulus he gave to his son. As secretary of the Research Defence Society from its foundation in 1908 till his death in 1926, Stephen Paget was indefatigable in serving the cause of experimental medicine. Prof. Turner recalled his labours during the late war when attempts were being made to discourage antityphoid inoculation and Paget worked to the limits of his strength in delivering lectures to the troops in training. Poor health again interrupted his service as director of the Anglo-Russian Hospital in Petrograd but up to the end of his life he used all his energy in the work he had chosen—work in which his object was always to see fair play to put the real facts squarely before his hearers and to inform them of what was often unknown and ill understood. That is essentially the honesty of which his father spoke and it is the enduring honesty of science.

INTER-DEPARTMENTAL COMMITTEE ON ABORTION—This committee which has been set up under the chairmanship of Mr. Norman Birkett, K.C., to inquire into the prevalence of abortion and the law relating thereto and to consider what steps can be taken by a more effective enforcement of the law or otherwise to secure the reduction of maternal mortality and morbidity arising from this cause, had a preliminary meeting and will shortly proceed to hear evidence. Communications may be addressed to the secretary, Committee on Abortion, Ministry of Health, Whitehall, S.W. 1.

SPECIAL ARTICLES

THE LISTER INSTITUTE

A YEAR'S INVESTIGATIONS

(Concluded from p 1422)

New growth factors in aqueous yeast extracts—Dr Macrae and Miss C E Edgar have shown that aqueous yeast extracts contain two factors, besides vitamin B₁ and lactoflavin, necessary for the growth of rats. One of these may be distinct from vitamin B₆, as described by György.

Chemistry of vitamin B₁—Extending their earlier work in Edinburgh Dr Todd and Dr F Bergel have completed a synthesis of aneurin (vitamin B₁). The synthetic product was identified with the natural vitamin by chemical and biological methods and the synthesis of a number of related compounds has been undertaken with a view to determination of the structural features essential for antineuritic activity.

Essentials for reproduction—Miss Hume and Miss H Henderson Smith have continued their study of the dietary deficiency in rats which affects their breeding capacity, the full term young dying in utero or failing to survive after they are born. Preliminary work by Dr Todd and Dr Bergel having confirmed the value of rice germ oil as a starting material for the isolation of the anti-sterility factor (vitamin E), the investigation of the unsaponifiable fraction of this oil as well as of the more commonly used wheat germ oil has been taken up in collaboration with Dr H Waldmann and Dr T S Work. From rice germ oil several crystalline alcohols have been isolated and the various products are at present being tested biologically. It is not yet possible to state definitely whether or not any one of them represents the pure vitamin.

Vitamin C requirements—Mr S S Zilva, D Sc, has studied the relationship of the intake of ascorbic acid to the vitamin C content of the "selective" organs and other tissues of guinea pigs, to their susceptibility to scurvy, to the urinary excretion of ascorbic acid, and to their general well being.

He found that in order to attain the maximum concentration in the tissues ten times the protective dose had to be given. Only traces of the vitamin were established in the "selective" tissues when a daily dose 2-3 times as great as the protective dose was administered. Guinea pigs, the tissues of which contained these minimum amounts of vitamin C, were, however, observed to live for a number of years during which time they attained very high weights. Furthermore the time taken by guinea pigs to succumb to scurvy when placed on a scorbutic diet was not appreciably different, whether the tissues carried their maximum load of ascorbic acid or whether only traces of it were present in them, prior to the animals being deprived of the vitamin. The accumulated vitamin C in the body of the guinea pig, therefore, does not act as a store in the true sense of the word.

The results of this investigation are in accord with the general observation made by Zilva and S W Johnson some years ago on human beings and lend support to the view that there is a wide margin of "unsaturation" with vitamin C which has no obvious detrimental effect on the health of the individual.

Vitamin C and cataract—The presence of vitamin C in the aqueous humour and lens in relatively high quantities has attracted the attention of those interested in the aetiology of cataract and contradictory views are held concerning the significance of this fact. Dr Johnson has devoted his attention to the fate of the ascorbic acid in the humours and lens of

the eye of the guinea pig in the process of depletion of vitamin C, but his results suggest that the deprivation of guinea pigs of vitamin C has no direct bearing on the aetiology of cataract in these animals.

Synthetic ascorbic acid in canning fruits and vegetables—It has previously been shown that it is possible to add ascorbic acid to fruits and vegetables before canning without incurring serious destruction of the acid during the process. Preliminary work by Dr Zilva and Mr T N Morris has been carried out on the stability of the acquired antiscorbutic potency of these final products. Apples canned in January, 1935, were tested in September, 1936, by the biological method, and no perceptible loss in activity during storage was recorded.

CALCIFICATION

Calcifying mechanism of bone—Previous work has shown that the activity of the calcifying mechanism of the hypertrophic cartilage of the bones of rachitic rats is generally lower than in that of normal embryonic bones. Is this decreased activity merely a sequel to the failure of the cartilage to become calcified or is it partly responsible for this failure? Prof R Robison, F R S, and Miss J Barnett have observed a very striking increase in the activity of the calcifying mechanism in bones of rachitic rats which have received a single moderate dose of calciferol (5-30 international units vitamin D) within 24-48 hours of death. Calcification of these bones in vitro occurs at unusually low levels of calcium and phosphate concentrations, even lower than those required for normal bones.

It has been shown by other workers that the type of rickets induced by addition of beryllium salts to the diet does not respond to vitamin D therapy. In agreement with this it has now been found that the administration of very large doses of calciferol (up to 100,000 I U) shortly before death produces no increase in the very low activity of the calcifying mechanism of the bones.

Calcification of the aorta—Prof Robison and Dr M Laskowski (Warsaw) have completed their experiments on changes in the aorta in hyper-vitaminosis D. Calcification of this vessel occurs very rapidly in rats receiving large doses of calciferol with a diet of high calcium content but may remain absent if the calcium intake is sufficiently reduced. Experiments made with the aorta of these rats have failed to produce any evidence of changes in the organic tissue before deposition of calcium salts but facilitating such deposition, analogous to the effects observed in bone. The results must be taken as supporting the view that calcification of the aorta in hypervitaminosis D is primarily the result of supersaturation of the blood with calcium salts.

Lactation—Dr G A Grant has investigated the influence of certain hormones in reinstating lactose synthesis in vivo in regressing mammary glands of female guinea pigs which have just ceased lactation. The lactogenic factor, prolactin, induced these regressed glands to produce only a limited secretion of a milk like fluid of very low lactose content (0.2-0.4 per cent). However, active secretion of milk containing 2.5 per cent lactose is produced by prolactin, if the secretory cells of the acinar tissue have undergone a reconditioning process through treatment of the animals with oestradiol and progesterone. Certain substances, for example diphenyl α naphthylcarbinol which do not possess the phenanthrene nucleus characteristic of the sex hormones,

also caused mammary growth in male animals though the possibility of this being an indirect effect on the general endocrine system requires further examination

SERA AND VACCINE

Specific antigen of *Shiga* bacillus.—At Elstree Mr W T J Morgan Ph.D. has continued his investigations into the nature of the specific antigen of *B. dysenteriae* (Shiga). It has proved possible to recover the bacterial antigen in a form which can be considered to be its natural state. It is a poly-saccharide-lipoid complex which readily engenders in the rabbit specific agglutinins and precipitins for *B. dysenteriae* (Shiga). The polysaccharide represents about 40 per cent of the antigenic complex, an account of its chemical structure was given in last year's report.

Spoore-bearing anaerobes.—Mr D W Henderson Ph.D. has continued his study of the protective substances in specific antibacterial sera which control experimental infection with *Clostridium oedematis maligni*. His observations suggest that antibacterial prophylaxis may find practical application in the control of infections associated with this organism.

Meningococcal infection.—Dr G F Petrie has confirmed the statement that an inoculum containing a comparatively small number of living meningococci suspended in a solution of mucin is lethal to mice by intraperitoneal injection. It is now possible to estimate without difficulty the relative virulence of meningococcal strains by means of the mucin technique. Thus a Group I culture maintained under routine conditions for the past three years has proved to be as virulent as several freshly isolated strains. It is intended soon to investigate the therapeutic action of antimeningococcus sera in mice with the aid of mucin.

Type specific antistreptococcus sera.—Dr Petrie and Dr Henderson have immunised rabbits and horses with three serological types of streptococcus which are often present as pathogenic agents in a variety of streptococcal infections in man. The rabbits have responded satisfactorily as judged by their agglutinin titres, but the horses have yielded sera of much lower titre. Experiments are to be carried out in mice to ascertain whether the protective action of the experimental antistreptococcus sera is strictly type specific. Preliminary tests indicate that the limits of error are wider than those of similar tests in use for titrating antipneumococcus serum Type I.

Stabilising action of glycerin on toxins and sera.—The experience of the past fifteen years at the serum department has proved that the addition of 50-60 per cent glycerin to tetanus toxin has a remarkable stabilising action on it and thus facilitates its use as a laboratory standard in routine tests of samples of antitoxin.

Within recent years the principle has been extended to the toxin of *Cl. welchii* and to dysentery toxin (Shiga). Technical difficulties have hitherto precluded the application of the method to diphtheria toxin but Dr Petrie has now prepared a glycerinated toxin by a simple method which permits of some degree of purification and of a threefold concentration of the lethal toxin. The 1 + dose of this preparation is 0.0133 c.c.m. and the average lethal dose is 0.0003 c.c.m. for guinea-pigs of 250 grammes. The addition of glycerin to antitoxic and antibacterial sera is known to have a stabilising influence on the specific antibody and the method has been applied to most of the laboratory serum standards in use in the department. Glycerinated preparations of this kind possess the great advantage that they can be stored at -10°C .

Dr Petrie and Dr Morgan have made further observations on the rate of destruction of the protective

antibody in batches of natural and concentrated antipneumococcus serum Type I, on storage. The concentrated product loses potency much faster than the natural serum, and the loss takes place mainly during the first year. Dr Petrie has begun similar observations on the stability of the specific antitoxin in anti-dysentery serum (Shiga).

Elementary-body suspensions in Jennerian prophylaxis.—Behrens and Neilson in 1935 described a method for purification of vaccinia virus by use of electric precipitation of the associated proteins in a suspension of vaccine pulp. Dr D McClean has studied this method and its application to the production of bacteria free suspensions of elementary bodies suitable for intracutaneous injection in Jennerian prophylaxis. It appears that the storage of elementary body suspensions of vaccinia prepared for clinical use is unlikely to present serious difficulties.

TISSUE PERMEABILITY AND LOCAL IMMUNITY

Dr McClean has completed the observations begun by Dr Favilli (Perugia) and himself on the relation between tissue permeability and local immunity to infection.

The inhibition of the diffusion of crude tests extract in the dermis by Boerdefka's "antivirus," plain broth, and various substances known to reduce the permeability of the cell was reported by Favilli and his collaborators. This has been confirmed using purified preparations of the diffusing factor from the testis (Culturo filtrates from certain invasive bacteria cause a dramatic increase in the permeability of the tissues and it has been shown that the diffusion of the purified spreading factors obtained from these filtrates is similarly inhibited by the same agents. The mechanism of this inhibition has been investigated and it appears that it is the inflammatory cellular response provoked by the injection of "antivirus" plain broth, and other substances, which renders the tissues less permeable to these diffusing factors whether they are derived from the testis or from bacteria. These observations supplement the work of Menkin on the local fixation of inflammatory processes, and they indicate that local immunity may be explained at least in part by a non-specific reduction in the state of permeability of the tissues. They also indicate the importance of the balance between the diffusing activity of invasive bacteria and the reduction in local permeability that results from the inflammatory response by the host.

Apart from the purely local reaction it is known that the diffusing factors of bacterial origin are antigenic and provoke the appearance of neutralising substances in the serum. Preparations are being made for a serological investigation of the relation between purified diffusing factors derived from different bacterial species such as *Staphylococcus Cl. welchii* and *Cl. chauvoei*.

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

TOWARDS A NATIONAL PUBLIC HEALTH POLICY

AN important step in the direction of an agreed programme between organised medicine and the State for the care of the indigent sick was taken on May 24th when the house of delegates of the Medical Society of New York accepted a report of its committee on the provision of medical care. The report accepted as a principle that the health of the people is a direct concern of the Government and a national public health policy directed toward all groups of the population should be formulated. This extension is to be governed by the approval of the local medical profession and is to incorporate to the greatest possible extent the services of the general practitioner.

in preventive medicine. Among the practical proposals designed to carry out these principles are the following:

"That the first necessary step toward the realisation of the above principles is to minimise the risk of illness by increasing preventive efforts through extension of public health services, federal and local.

"That an immediate problem is provision of adequate medical care for the medically indigent, the cost to be met from public funds.

"That public funds should be made available for the support of medical education and for studies, investigations and procedures for raising the standards of medical practice. If this is not provided for, the provision of adequate medical care may prove impossible.

"That public funds should be available for medical research as essential for high standards of practice in both preventive and curative medicine.

"That public funds should be made available to hospitals that render service to the medically indigent and for laboratory diagnostic and consultative services. That these consultative and laboratory diagnostic services shall be established only in regions where the medical profession approves the need for same, and after consultation with the local medical profession in the area affected.

"That in the allocation of public funds existing private institutions should be utilised to the largest possible extent and receive support so long as their service is in consonance with the above proposals."

These proposals, along with a request for a working definition of the term "adequate medical care," were before the house of delegates of the American Medical Association when it met last week.

THE TRAILER

The automobile trailer, like the house sparrow, is said to have been imported from England. In recent years these mobile homes have manifested a remarkable creative faculty. Since Mr Sherman, whose money came from his father's vaccine laboratory in Detroit, exhibited the first trailer at a Detroit auto mobile show in January, 1930, his business has grown by leaps and bounds. Last year he sold 6000 "covered wagons." Total factory production was about 35,000, and the *Automobile Daily News* estimates that 160,000 trailers were on the road.

A survey of the American Municipal Association, the Society of Planning Officials, the American Public Welfare Association, and the National Association of Housing Officials arrives at the estimate that this summer there will be 400,000 automobile trailers in use, housing 1,250,000 persons. It is not necessary to accept Roger Babson's forecast that within twenty years half of the population of this country will be living in trailers before we convince ourselves that trailer housing constitutes a genuine public health problem.

When is a trailer a house? When its wheels have been removed (as one of our recent ordinances decrees) or when it has stood for a specified number of days in one particular spot? Most trailers have no refrigeration—what happens to the food and milk carried on board? The common solution of this problem has led to the nickname of "tin can tourists" being applied to trailer folk. Above all, how shall the trailer dispose of its garbage and sewage?

Florida welcomes trailers and provides comfortable sanitary trailer camps equipped with running water, sewerage connexions, electric current, shower baths, and toilet facilities. Rates for a site in such camps vary from one to ten dollars a week. If the trailer contains children Florida charges a licence fee of 12 dollars towards the cost of their education. In some of the camps doctors, themselves living in trailers, are licensed to practise medicine among the rheumatic, bronchitic, sinus infected refugees from northern cold and snow. On New Year's Day trailers crossed the State line into Florida at the rate of 25 an hour.

Northern and western States have not all proved themselves as adaptable to the refugees from summer heat. Municipal ordinances, it is whispered, have been devised ostensibly to protect the public health but actually in the interests of hotel proprietors and real estate firms. Unable to rely on finding a camp with sewerage provisions, the trailer builders have resorted to a number of ingenious devices. There is the chemical toilet, of course, whose treated effluent is probably harmless if it is properly treated. Or there may be a simple container with provision for "decorising" until opportunity for decent burial occurs. A modern contrivance makes use of a waterproof paper bag which can be securely sealed after use and disposed of at leisure.

There is at least one travelling tuberculosis sanatorium that provides a perpetually ideal climate and the distraction of travel, as well as all modern medical care and (it is said) adequate rest for the patients.

IRELAND

(FROM OUR OWN CORRESPONDENT)

A SEQUEL TO INOCULATIONS THE JURY'S VERDICT

THE inquest at Ring, co. Waterford, on a girl of 12, who had died from generalised tuberculosis following an immunising injection against diphtheria (see *Lancet* May 29th, p. 1305), was continued on June 10th and concluded at the district hospital, Dungarvan, on June 12th. Dr Walsh, the acting coroner, put the following questions to the jury: (1) When, where, and from what cause did the deceased die? (2) Was the ulcer on her arm a tuberculous ulcer? (3) If it was a tuberculous ulcer did the general tuberculous condition from which she died spread from this? (4) If it was a tuberculous ulcer, did the microbes causing it enter the body at the time the child was inoculated against diphtheria? (5) If they did enter it at the time what was their source and how did they come to be injected?—With regard to his last question the coroner said that the lines for an investigation with any hope of reaching a solution seemed to him to be almost endless. It must needs be a long, searching, and highly scientific one, more properly carried out, in his opinion, by a body of scientists than by a coroner's jury. "If you believe," he said to the jury, "that you are not in a position to give an opinion as to the origin of the tubercle bacilli, you will say so. And I cannot see how you are in such a position." The jury then brought in a verdict as follows:—

"That we unanimously agree with the medical testimony that Siobhain Kennelly, died at Knockenpower on April 20th, 1937, from toxæmia and purpuric hæmorrhage consequent to general miliary tuberculosis infection and that we are of opinion, according to the evidence placed before us, that the tuberculous condition was originated by the inoculation of prophylactic into the right arm of Siobhain Kennelly in November 1936 and that we are of opinion that the contents of the 25 c.c. bottle of prophylactic labelled T A F Burroughs Well come, from which a portion of the material was extracted by Dr Daniel McCarthy for the purpose of the aforesaid inoculation, contained tubercle bacilli, and that the inoculation was carried out by Dr McCarthy according to the most approved surgical technique. Every precaution was taken by him and by those who assisted him to guard against infection arising from contaminated surgical applications and we exonerate them from any blame in this matter."

Giving evidence about other children at Ring College who suffered after a similar injection, Dr P. Kiely (Cork) said he had examined 10 of the original 11

children and found practically all the primary lesions healed, and in all the condition of the glands greatly improved. Replying to counsel he said that in his opinion the future development of the children would be entirely favourable.

TREATMENT OF TUBERCULOSIS

Speaking at the annual meeting of the Royal National Hospital for Consumption for Ireland on June 10th Dr T G Moorhead drew attention to the recent addition of a fully equipped operating theatre. The facilities for operative work were now as good as in any hospital in Great Britain or Ireland. He added that it had been stated that it was proposed to establish sanatoriums in every county in the Irish Free State. He thought that if that were so they should limit their activities to incurable cases. If they were to compete with such institutions as those at Newcastle and Peamount they would do more harm than good. He understood that there was also a project to establish a central surgical hospital for tuberculosis. That might be a good thing but it was a better thing to have treatment carried out in one institution.

MEDICINE AND THE LAW

Dismissal of Officials under Lunacy Act

THE tenure of officers appointed under the Lunacy Act has been examined afresh by the Court of Appeal in *McManus v Bowes*. Section 278 of the Act requires the visiting committee of every mental hospital to appoint a medical officer and adds that the committee may remove any person appointed under this section. Does the word remove mean remove at the committee's pleasure? If a statutory authority has power to appoint and remove officers, is it entitled to dismiss at a moment's notice? This said Lord Justice Slesser is a matter of great importance because it goes to the root of the tenure of everyone employed under the Lunacy Act.

Dr Hugh McManus formerly assistant medical officer of the Park Provost Mental Hospital, Sherborne St John Hampshire claimed damages against the Hampshire Joint Mental Hospital Committee for wrongful dismissal and also sued for the return of his superannuation contributions. He had originally sued Dr R F B Bowes the former medical superintendent of the hospital on the ground that Dr Bowes had unlawfully procured the committee to dismiss him. At the trial before Mr Justice Macnaghten it was held that there was no evidence to go to the jury in support of the allegation against Dr Bowes. On appeal the Court of Appeal likewise released Dr Bowes from the proceedings for want of evidence against him. The case was then dealt with on the issue of the power to dismiss without notice. It was argued for Dr McManus that there was nothing in the reported cases which should incline the court to interpret remove as remove at the committee's pleasure. Lord Justice Macnaghten was puzzled by the fact that the committee had purported to give Dr McManus three months' salary in lieu of notice. Under what power did the committee do so? Could the district auditor have so charged this sum as an illegal overpayment? Lord Justice Slesser asked whether if an official had a two year contract he could still be dismissed at pleasure? After full argument the Court of Appeal was unanimously of opinion that the committee had power under the Lunacy Act to remove one of its servants at will. The judge at trial had ruled that the plain-

tiff's claims were barred by the Public Authorities Protection Act 1893 because they were not brought within the statutory time-limit of six months. The Court of Appeal declined to interfere.

Substantial Damages for Release of Mental Patient

As the medical profession is well aware, there can be heavy damages against a doctor whose certificate causes a mental patient to be confined or retained in an institution. The substantial award of £3500 has now been given in the converse case of a too early release. At Liverpool assizes last week Mrs. Bertha Holgate with her husband successfully sued the Lancashire Mental Hospitals Board and two doctors of the Calderstones Institution near Blackburn. The defendants she contended had committed a breach of statutory duty and had been negligent in licensing John Lawson a mental defective to be absent from the institution. Lawson had attacked her at her home and she had suffered serious injuries. Sir Patrick Hastings, K.C. who opened the plaintiff's case with characteristic vigour stated that Lawson aged 29 was a dangerous criminal who had been charged with housebreaking, larceny, assault, attempted rape and robbery with violence. Lawson had been an inmate of Rampton Asylum. From this State institution he was transferred to Calderstones on the assumption that his condition was improved. Lawson's brother (described by counsel as a working man with very little leisure to look after anybody else) applied for his temporary release on licence and assured the committee that the patient would remain under his personal supervision. John Lawson went to Mrs. Holgate's house, said he was hungry and asked for a cup of tea. When her back was turned, he picked up a piece of wood, came up behind her and struck her on the head. Her skull was fractured and her wrist and hand were also injured. One year of her life had been wiped out and no one could say how many more years she might not lose through her injuries. The two defendant doctors, Dr F A. Gill and Dr G S Robertson were respectively the superintendent and deputy superintendent at Calderstones. Dr Robertson had signed the licence. Sir Patrick Hastings emphasised that only the superintendent had authority to sign.

Counsel for the defendants reminded the jury that Dr Gill had spent a lifetime in the care and treatment of mental deficiency and Dr Robertson had 12 years' experience of such work. There were seven offences on record against Lawson but on five of these occasions he was either bound over or put on probation; all the cases except the last had occurred before he was 18. He had shown no signs of violence at Rampton Asylum, his transfer to Calderstones indicated a progressive improvement and it was reasonable in view of his recent history to let him out for a short time to see how he behaved under proper supervision. The committee had seen and questioned the brother, it considered the accommodation and supervision would be adequate. Finally it was urged that the two doctors had acted upon honest belief based upon their medical skill and experience. Error of judgment was not negligence. The jury however awarded £3,500 to Mrs. Holgate and £700 to her husband. The defendants had paid £2000 into court with denial of liability. This sum was ordered to be paid out to Mrs. Holgate in part satisfaction of her award and judgment was given in accordance with the jury's findings. As the judge observed in the course of his summing up it is easy enough to be wise after the event.

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations. Each contributor is responsible for the section for a month, his name can be seen later in the half yearly index

BY TWELFTH MAN

III

Sir Auckland Geddes advised his medical audience in Edinburgh to cease "their fear of the non rational." Such advice might be thought superfluous in our day when the behaviourists maintain that there is no non material element in our make up, when determinists declare that we are impelled by a *vis a tergo* which is both incalculable and irrational, and when the Freudians insist that our conduct is determined not by reason or free-will but simply by our instinctive desires. He was not, however, urging the claims of irrationalism as a satisfactory philosophy but pointing out that there are many facts and many phenomena which reason cannot elucidate. Such a view has become a commonplace of twentieth century science. Modern men of science, says Bertrand Russell, "believe that ascertainable truth is piecemeal, partial, uncertain, and difficult." It is possible to be grateful for this new found humility of the scientists while still believing that reason remains man's guide to as much truth as is ascertainable, that his reason is free and may still be used to control his instinctive desires

* * *

G. K. Chesterton in his autobiography has an amusing description of the discussion which took place in the village of Beaconsfield concerning the nature of the proposed war memorial. G. K. C., as might be expected, argued strongly for a cross but the "local doctor, an admirable physician but a sceptic of rather a schoolboy sort, observed warmly, 'If you do put up a thing like this, I hope you'll stick a light on it, or all our cars will smash into it in the dark.'"

This is a perfect illustration of the practical, the materialist approach to life's problems which is the normal attitude of the doctor. There is no need to defend this outlook in a medical journal, its virtues shone for us like a good deed in a naughty world. The limitations of such an approach are less obvious, for we are mostly 'sceptics of rather a schoolboy sort.' We were trained to believe that the intangible was non real, the invisible non-existent, and what we could not explain was not merely inexplicable but irrational also.

It is difficult to slough off habits of thought which have dominated us for generations, but if, while still retaining unrepentantly our belief in rationalism as a working day philosophy, we could acquire something of the spirit of our modern physicist philosophers, we might get with it incalculable gain. "Come down to brass tacks," declares our Beaconsfield doctor, "granted that there is this new spirit in modern science, what can it profit clinical medicine which has no concern with the fourth dimension?" While we await an answer to this pertinent question from some undiscovered clinical genius, let me attempt an inadequate reply. I believe that in each age there are a few dominating ideas which permeate and fashion the thought of the day. These ideas are valuable not because they enunciate fresh truth but because they reveal new aspects of truth. I believe that clinical medicine stands to day in urgent need

of such reinterpretation. There are hosts of new facts, imperfectly digested, which demand new generalisations and such generalisations would alter profoundly our conception of disease processes in the individual. But even if this new comprehension is denied us, I think the modern scientific spirit might still do much for us. It would make us more receptive of new ideas in medicine and more distrustful of new remedies. It would make us less satisfied with the diagnostic labels which we attach to patients and less disappointed if a piece or two of the jig saw puzzle is missing, as it so often is. It would help us to look at disease constitutionally, to regard it as a reaction of the whole man, mind and body—an individual reaction. It would kill forever those monstrous text books of differential diagnosis that depend on an analysis of symptoms—*katabolic* and not *anabolic*. It would give us a juster appreciation of the results of laboratory research and an enhanced ability in the fitting of these new facts into the mosaic of our clinical conceptions. It would make us more critical of our own dogmatism, more aware of our enormous capacity for self-deception. It would keep Cromwell's cry ringing in our ears, "Gentlemen, I beseech you, by the bowels of Christ, to remember that you may be mistaken." This would be no mean harvest. I may be wrong, but I think it has been possible to see the stirrings of this new spirit during this last decade.

* * *

The recent death of Miss Moberley recalls an incident which illustrates well our changed attitude to non rational experiences. Thirty six years ago¹ Miss Moberley and Miss Jourdain were on holiday in Paris. They were women of high intelligence and the successive principals of St. Hugh's College, Oxford. Neither of them had any specialist knowledge of French history. They were walking one afternoon in the grounds of the Petit Trianon at Versailles when they were met and addressed by persons wearing the costume of 1789, some of those persons were visible to one of them, others to both. They passed by woods that no longer exist, saw a man sitting by a kiosk which has disappeared long ago, and were accosted by a footman who emerged from a door in the palace which, through the destruction of a staircase was built up nearly a hundred years ago. At the time the ladies noticed nothing peculiar in their experiences beyond a strange feeling of depression. It was only when discussing some weeks later the events of the afternoon that they became impressed by the strangeness of what they had seen. Patient research in the years that followed revealed that the geography of the place, as they described it, was as it had been in the days of Marie Antoinette, that the lady seen by Miss Moberley was Marie Antoinette herself, that the dresses were in detail what they would have been in 1789. There is much quietly described corroborative detail in the book, it makes fascinating and unusual reading.

It is not difficult to imagine what the general reaction to this recital would have been thirty years ago—but to day J. W. Dunne, in an introduction to the book writes, "Hence, if Einstein is right the

¹ "An Adventure" By C. A. F. Moberley and F. F. Jourdain London 1931

contents of time are just as real as the contents of space. Marie Antoinette body and brain is sitting in the Trianon garden now. What does that now mean? It is a four dimensional now such as would be employed by a super mind which could perceive Marie Antoinette and you (who are reading this) as equally present to perception. A dreamer's attention can travel to and fro in the physicist's alleged four dimensional time. Granted this absorption in that particular part of the past, anyone who is capable when awake of mental time-travelling combined with telepathy would be likely to see what these two ladies saw through the eyes of any persons who walked in that garden in the year 1789.

* * *

This adventure has one curious interest for the physician. It resembles the sort of visual and auditory aura which sometimes accompany an epileptic fit. James Collier described thus the aura of a patient of his who suddenly found himself approaching a level-crossing in a picturesque village in high sunlight. Out of the little guard house on the farther side came a woman dressed in the conical beaver hat and scarlet cloak of the Welsh national dress, who greeted him with a smile. He hastened forward to meet her but found the gates rapidly closing upon him. As they closed but before they touched him he lost consciousness. In this case the hallucination was always the same in every detail and in each fit. Moreover both Miss Moberley and Miss Jourdain experienced an extraordinary depression during the incident which in spite of every effort steadily deepened. I am not suggesting that both these ladies had epileptic attacks with an identical aura and at the same moment, but would our physicist-philosophers regard an epileptic attack as an explosive escape into fourth dimensional time?

* * *

The rôle of the expert in human affairs becomes an increasingly important one. With its increasing importance comes a distressing tendency for the expert to pontificate outside his own subject. When I read statements taken from experts found wandering but still capable of speech I recall the remark of Hanoverian George as he surveyed his troops before battle: I don't know what they'll do to the enemy but, by God, they frighten me.

The expert who uses his reputation to buttress an opinion which does not rest on the foundation of his special knowledge sins against the light. Examples of this occur readily to the mind. Doctors err frequently in the law courts where the expert medical witness is easily tempted. One of the less offensive instances was that of a distinguished forensic pathologist who gave his opinion as to whether or not the sound of a falling body could have been heard by the driver of a car. It matters not at all whether the medical jurist was right or wrong because his evidence on such a matter is of the same value as the least intelligent layman's—neither more nor less. But to day the opinion of doctors is invited both individually and collectively on many matters outside a court of law which are of national social and political importance. An enumeration of such subjects would include malnutrition, population, the birth rate, birth control, noise, tests for drunkenness, road accidents, the campaign for physical fitness, corporal punishment, euthanasia, war and peace, and many another problem even when specific questions of public health are excluded.

If doctors are to express an opinion on these and kindred subjects there will be general agreement that they should abide by the rules governing the conduct of experts on such occasions—viz (1) they should have a specific contribution to make (2) this contribution should rest on facts within their own knowledge and that of their colleagues (3) if their opinion should not coincide with informed medical opinion it should be so stated (4) if the subject should be one on which they have no expert knowledge it should be made clear that they are expressing an individual opinion which is of equal value with the opinion of Mr Smith. Although no one will quarrel with these rules I think it could be shown if one had the time and a gift for patient research that doctors both individually and collectively have published on all the subjects mentioned above opinions which are no more than the expression of a personal bias. I recall two recent examples of this.

* * *

There is a suggestion as all my readers know that the level of the alcohol in the blood should be used as a test of incapacity to drive in persons charged with being drunk in charge of a car. Some years ago an eminent surgeon who is also an ardent temperance propagandist wrote to the *Times* a letter which introduced this subject for the first time to the general public. The *Times* obviously impressed with our colleague's surgical distinction printed his letter in the place of honour on the middle page and his readers were no doubt equally impressed by his propaganda on behalf of this test. They did not know for he did not tell them that while biochemical assays are sufficiently difficult to interpret in the courts of medicine in the courts of law they darken counsel and confuse judgment. They did not know nor did he tell them that as a test for driving incapacity such examinations have in the opinion of many doctors about the same value as the olfactory evidence of an anomic constable. Nor was he content with this but he popped nimbly over a neighbouring hedge into the lawyer's field and said that any man who refused to have such an examination made when charged with such a misdemeanour stood almost self convicted! This remark must have caused laughter in the Inns but terror in the public houses—which was perhaps what our temperance propagandist intended.

* * *

A well known physician wrote to the *Times* a few weeks ago insisting that the cause of gastric disorders in London busmen was an insufficiency of vitamin B in their diets. This I should take to be in flagrant disregard of rules 2 and 3 quoted above. Let the busman eat brown bread. Their ulcers would be prevented and we might infer the buses would quickly be rolling down Regent street again. Vitamin B not only cures constipation prevents intestinal cancer but it is also a dramatic solvent of industrial disputes. Next day to his great indignation but to my great delight, he was confronted by another gentleman also straying from his own field. A distinguished member of the advertising business (not let me hasten to assure the cynical of our own profession) replied to him in a letter which outlined concisely orthodox medical opinion on the subject.

Sir A B a physician of repute
Went out to settle Bism's bus dispute
Too lad. He met Sir Advertising Jim
Who without much ado did settle him

CORRESPONDENCE

THE OVER TREATMENT OF GONORRHOEA

To the Editor of THE LANCET

SIR,—Mr Nicholls's letter in your issue of March 20th was one that has long required writing, and I should like therefore to congratulate him on his courage in attacking an evil which we all recognise. I fear however that unless a miracle happens his voice will be as "the voice of one crying in the wilderness," for the root of the evil lies rather in the system of treating venereal disease than in the individuals practising it. He puts his finger on the weak spot when he says "gonorrhoea has been withdrawn from the circle of hospital life and wedded to syphilis (an unhappy and incompatible match), and they live apart in a dark and uncritical world of their own."

The trouble is the training of the venereal specialist, and it is a curious irony of fate that this odd hybrid, whom Mr Nicholls so justly condemns, should have been made possible by John Hunter, the greatest name in British surgery, and the greatest name on the staff of Mr Nicholls's own hospital. Hunter, experimenting on himself in 1767, persuaded the world that syphilis and gonorrhoea were the same disease. It was therefore logical for one man to specialise in this disease. Philippe Ricord exposed the fallacy in 1837, yet we still talk about "venereal disease" in the singular, and we still seem to think that two dissimilar diseases—one, according to Osler, requiring the widest possible knowledge of internal medicine, the other obviously needing an expert acquaintance with urology—can be adequately treated by a junior official with very limited experience of either.

Venereal disease has always been the cinderella of medicine, and the only hope of rescuing it and its exponents from this lowly position is to restore syphilis to general medicine and add gonorrhoea to urology, the branch of surgery to which it logically belongs.

At present the treatment of venereal disease is a blind alley occupation. Those in charge have no chance of promotion to the medical or surgical staff of their respective hospitals. They have no incentive to enlarge their horizon, and as a consequence the following is the sort of thing that happens. A patient was treated for six months with sounds as a case of stricture. At the end of this period, getting no better, he was seen by a urologist who passed a cystoscope without any difficulty, and discovered he had cancer of the bladder which by this time had become inoperable. Anyone with the most elementary knowledge of surgery could not have committed such a tragic blunder, yet it happened at one of our best known venereal clinics. It is inadequate surgical training that makes possible the over-treatment by irrigation and the mangling of urethras with dilators that one now sees going on in so many of our venereal clinics. Such treatment would not be possible in any clinic where men with real surgical minds are in control. A man professing to be an expert on gonorrhoea ought to be able to use a cystoscope, do an internal urethrotomy, or operate on a prostatic abscess instead of allowing it to burst. He ought to be able to do a salpingectomy or cure a cervical tear when necessary.

How many of our so-called venereal experts are capable of performing these simple operations? Hardly any. And the reason is that they have been

trained on entirely wrong lines, acquired the mental outlook of the old dead and gone regimental medical officer instead of that of the urologist. Is it too late to hope that the treatment of gonorrhoea may be rescued from the dead hands of this "service" tradition, and allowed to develop on sound surgical lines?

I am, Sir, yours faithfully,

J. JOHNSTON ABRAHAM

Queen Anne-street, W. June 14th

DIAGNOSIS AND TREATMENT OF GASTRIC AND DUODENAL ULCER

To the Editor of THE LANCET

SIR,—I should like to suggest to Dr Duncan Leys that he should use a really delicate test for occult blood for a year. I am convinced that he would never go back to the rough methods used in most English laboratories. There is no analogy between the Fehling reaction for sugar and the tests for occult blood, because normal urine contains traces of sugar, so that a test is required which gives a positive reaction only with a percentage of sugar greater than normal. But normal stools contain no blood if there is none in the food, so the more delicate the test the more valuable is the information it gives. Every year I see at least half a dozen cases of cancer missed and numerous patients with an active ulcer said to be healed because a report of no occult blood has been received, although when the examination is repeated with Dr Ryffel's technique¹ it is positive. Properly done, a positive occult blood test is of more value than a negative X-ray examination, as it is positive in every case of cancer of the alimentary canal, and it rarely becomes negative with gastric and duodenal ulcers until after the nodule has disappeared. It therefore shows the need for further investigations in suspected cases of cancer of the stomach and colon when the first X-ray report is negative, and it gives the best indication we have as to when an ulcer has healed—short only of gastroscopy in the case of gastric ulcer.

The guaiac test has the great advantage over the benzidine test in giving no reaction with iron, whereas the latter is useless in the many cases of ulcer in which the presence of anaemia calls for the administration of iron, and the spectroscopic examination of a faecal extract for haematorporphyrin and acid haematin gives additional information of the greatest value.

I am, Sir, yours faithfully,

ARTHUR F. HURST

New Lodge Clinic, Windsor Forest, July 14th

SULPHÆMOGLOBINÆMIA AND METHÆMOGLOBINÆMIA AFTER SULPHANILAMIDE

To the Editor of THE LANCET

SIR,—In view of the communication of Dr Paton and Dr Eaton in your issue of May 15th and their letter published on June 5th, the following case in which sulphæmoglobinæmia and methæmoglobinæmia developed after the administration of Prontosil appears to be of interest.

A man aged 41 was admitted to Guy's Hospital on March 11th, 1936, for a chronic empyema of three months standing. A rib was resected on March 18th and 3 pints of pus were drained off. The pus was sterile on culture. The patient made satisfactory progress until March 27th

¹ *Ide Price's "Medicine"* 4th ed., 1933 p. 605

when he developed an acute tonsillitis. Hemolytic streptococci were grown from a throat swab. On March 31st the patient had a venous thrombosis in the left leg and on April 3rd he began to have rigors. On April 4th he developed arthritis of the right wrist and a blood culture at this date gave a heavy growth of hemolytic streptococci. On April 6th the hemoglobin was 58 per cent and the white count 11 000 cells per c.mm.

From April 6th to the 13th 5 c.cm. of protosol was given intravenously each day and 2 tablets of protosol per os t.i.d. After April 13th no further injection was given but the patient continued to take the tablets per os for a further few weeks. On April 9th the temperature remained normal and the patient was very much better. The white count rose to 22 000 cells per c.mm. and a blood culture on April 15th was sterile. During the severe stages of the illness the patient had a livid complexion, but this was attributed to the septicaemia.

Progress continued to be satisfactory until May 16th when the temperature began to rise again up to 100 F. each day. On May 20th the patient complained of pain in the right groin and later this spread to the knee. On examination there was evidence of psoas spasm and tenderness in the right groin and right loin. The presence of a psoas abscess was suspected. On June 10th treatment with protosol tablets was recommenced. The patient then became obviously cyanosed the lips ears and facial venules being of a leaden blue colour. There was no dyspnoea and the patient appeared unusually well in himself. Exogenous cyanosis was diagnosed and on June 15th Dr J. H. Ryffel examined the blood and reported: "The laked blood shows an absorption band in the red which gets smaller but does not disappear on addition of ammonium sulphide. The band appears to be due to a mixture of methemoglobin and sulphemoglobin."

Besides protosol the patient had been having amongst other drugs magnesium sulphate and phenacetin. On June 14th all these drugs were omitted. On June 21st the hemoglobin was 27 per cent. At this date the patient's colour had much improved although the cyanosis was still marked. Dr Ryffel again examined the blood on June 26th and reported: "The blood still shows a well marked band in the red not altered by ammonium sulphide. Therefore sulphemoglobinemia only. In the meantime oedema developed in the right loin and right thigh and it was thought desirable to perform an exploratory operation. In view of the patient's general condition he was given a blood transfusion of 300 c.cm. on June 26th and a second transfusion of 500 c.cm. on June 30th. On July 2nd a large psoas abscess was drained in the thigh. Hemolytic streptococci were grown from the pus. Following this the patient made satisfactory progress culminating in his discharge from hospital."

I am indebted to Dr E. P. Poulton under whose care the patient was and to Dr Ryffel for permission to publish this case.

Methemoglobinemia and sulphemoglobinemia in the same patient has also been described by L. P. Garrod (*Quart. J. Med.* 1925 19 80). In this case the methemoglobinemia was believed to be superadded to the exogenous picture by the excessive use of headache mixture and cleared up immediately on the discontinuation of the drug.

I am Sir yours faithfully

J. A. J. HAMMOND

Guy's Hospital, B.E. June 9th

TREATMENT OF ACUTE OSTEITIS

To the Editor of THE LANCET

SIR,—Owing to absence from home I have only just read Mr Saint's interesting lecture on Acute Osteitis published in your issue of May 22nd and 29th. His reference to a contribution of mine on the subject calls for some comment although I cannot here discuss all the points raised. If anyone who is interested will refer to my article they will find that two of the three patients who died were suffering

from virulent septicaemia and that immediate operation was undertaken because at that time I did not realise the value of delay in such cases. I am not suggesting that with expectant treatment the outcome would have been different but I do wish to emphasise that the initial septicaemia is by no means always mild, as Mr Saint appears to suggest and that a few days pre-operative treatment may be a life-saving measure. In this connexion there is no one who can find the records of Mr Tyrrell Graves' cases! They might be of great value. Since my article was published I have treated nine more cases on similar lines without a death.

On the exact extent of the local operation I do not wish to dogmatise but I am convinced that harm has been done in many cases by too radical interference. Our first object in a disease with a mortality so potentially high should be to save life. The principles of treatment should be operation at the right moment which in my opinion should not be within a few hours of diagnosis, adequate fixation of the part and infrequent dressing which can be secured by using B.I.P.P. As regards the latter agent I am in whole-hearted agreement with Mr Saint having used it constantly after my first trial of it in Mesopotamia in 1916.

The subject of acute osteomyelitis has been up for discussion at medical meetings on many occasions. I would suggest to Mr Saint that a statistical investigation by the Association of Surgeons into the results of various methods of treatment, would be of considerable interest.

One final question can Mr Saint give us the approximate duration of illness in each case before he operated?

I am Sir yours faithfully

Northampton June 14th

C. C. HOLMAN

A DEBT OF HONOUR

To the Editor of THE LANCET

SIR—The Southern Spanish Relief Fund whose hospitals for children in Almeria suffered severely in the recent German bombardment appealed through your columns on March 13th for the voluntary assistance of doctors. Five applications in all were accepted after irreproachable references from colleagues had been received and after two of the applicants had been interviewed by a leading London doctor. Four of these five had successively to be repatriated in their own and our interest leaving us with liabilities which amount in all to over £200.

I honour the kindly reluctance of reference writers to give information that will prevent acceptance of a colleague's application but I hope that your readers may feel the same kindly reluctance to let a compatriot suffer serious loss thereby. For I feel it impossible to charge expenses of the character incurred to a fund raised for the Spanish wounded women and children. Failing help they will have to be met from a private purse already depleted by running and raising money for the hospital. Any subscriptions for the relief of this personal liability should be marked medical and addressed to I. T. Marling Esq. F.C.S. The Hon. Treasurer Southern Spanish Relief 10 Old Jewry F.C.2. Should they exceed the total liability subscribers will be consulted as to the refund or redistribution of the balance.

I am Sir yours faithfully

GEORGE YOUNG

Director of British Hospitals, Almeria and Murcia

PREGNANCY TOXÆMIA

To the Editor of THE LANCET

SIR,—I have read with some interest Dr Theobald's paper in your issue of June 12th. Important as minerals and vitamins are to the economy—even in the non pregnant—I do not think their exhibition in pregnancy plays the part which Dr Theobald would have us believe. From his own account these substances do not prevent the occurrence of the pregnancy toxæmia, for signs appeared in 13 out of 50 cases treated. Since the incidence was much greater—more than twice as great—in the 50 not so treated, suggesting some effect, we must either conclude that the doses in the first 50 were insufficient, or that some other cause than a deficiency of these substances is at work in the production of the toxæmia of pregnancy.

Unfortunately, in his present paper, Dr Theobald does not consider other possible causes. He talks of the different protective substances associated with toxic symptoms. Attributing the difference in the incidence of "complications" in his two groups to the substances given in the one and withheld from the other, he asserts that the results of the dietetic treatment of these patients in the antenatal ward strengthen his assumption. "The symptoms," he says, "cleared up in every case." He believes, apparently, that these cases cleared up because of the dietetic treatment, and because of that alone. But, presumably, these patients were kept in bed, if that were so, the effect of rest in bed, per se, finds no place in his argument.

I do not propose to dissertate here on the effect of rest in bed, it will be admitted that rest in bed has some effect—even in patients suffering from the toxæmia of pregnancy. But it does not matter whether Dr Theobald's patients were kept in bed or not, I know from my own experience that putting toxic patients to bed and feeding them on water only—and in restricted quantity (to begin with 1 pint, or 1½ pints per 24 hours) flavoured with a little lemon and given a little glucose—restores these patients to the normal, the oedema disappears, and presumably the blood pressure if raised goes down. I give them no especial vitamins and no calcium, yet they get well. The treatment is essentially physical combined with starvation. But to day, when every disease is attributed to some biochemical aberration, and the patient is treated by the exhibition of some tablet or capsule, I do rather wonder whether the effect of rest in bed will be allowed to be a physical one. But if rest in bed acts physically, how does it do so? I state categorically that rest in bed, per se, prevents the toxæmia of pregnancy. It is for your readers to answer how it does so.

In line with this we find that dietary deficiency in pregnancy occurs without the appearance of the pregnancy toxæmia. Anæmic pregnant women appear immune from the toxæmia of pregnancy. Truly, eclamptic women are anæmic, but that is a result of the visceral impairment, not the cause of that impairment. In the same way we see that postpartum hæmorrhage is never followed by postpartum eclampsia. How does venesection prevent eclampsia—whether ante or post partum? By producing an anæmia? By its chemical or its physical effect? The danger of removing too much blood postpartum is puerperal sepsis, not the toxæmia of pregnancy (e.g. eclampsia). Truly the biochemical ingredients of the blood are of importance, but not in the prevention of the toxæmias of pregnancy.

May I remind your readers that man consists of a mass of cells, &c., that both the cells and the juices possess very definite physical qualities, and that not one of the vital functions goes on without the play of physical forces which the cells of the body engender, and that when these physical forces are insufficient or too great, physiological processes are disturbed, and interfered with. This is even so in the pregnant woman, it occurs irrespective of biochemical (vitamin) influences, it is a factor which those desirous of understanding the toxæmia of pregnancy and its prevention will be forced—by the *reductio ad absurdum* argument if by no other—sooner or later seriously to consider.

I am, Sir, yours faithfully,

Rugby, June 11th

R H PARAMORE

To the Editor of THE LANCET

SIR,—It is now over six years since I advocated in the *British Medical Journal* the continuous administration during pregnancy of calcium phosphate 15 grains three daily, together with a plentiful supply of green vegetables. I was and still am of opinion that the toxæmias of pregnancy are deficiency diseases.

The case for the continuous administration of calcium during pregnancy seems unanswerable. For nine months there is an enormous demand on the mother to provide calcium phosphate for the bones of the fetus, this demand has to be met in some way, either by an increased intake of calcium or by drawing on the mother's reserve of calcium, with disastrous consequences for both mother and child. Another well known fact is that there is a seasonal variation of the phosphorus and calcium content of the blood, the percentages being highest during the months of maximum sunshine, therefore during the winter, and especially the months following the winter, there is greater need of calcium than ever. This need for calcium coincides with the greatest incidence of eclampsia, according to Harrer of the New York Lying-in Hospital, who has shown graphically the incidence of eclampsia during ten years, and considers that the increased incidence in early spring is due to the cold and damp weather prevailing at that time (Williams's "Obstetrics").

We know that in chronic parenchymatous nephritis the calcium content is low, that nephritis and oedema have been successfully treated with calcium, and that calcium has a sedative effect on the nervous system and diminishes the permeability of the blood vessels, and we know that in some cases of uræmic convulsions the blood calcium is low. We know also that one cause of tetany is calcium deficiency, and curiously enough it has been noted that epidemics of tetany usually occur in the spring. These and many other reasons seem to indicate that large doses of calcium, in addition to the vitamins, are required to make up the maternal deficiency, and to prevent the so called 'toxæmias of pregnancy'. If in spite of these measures the patient shows signs of hyperemesis I would advise, in addition to the calcium phosphate and vitamins, giving dilute hydrochloric acid, preferably in the form of betaine hydrochloric and pepsin, of which there are several preparations on the market.

I am a little disappointed that this treatment has not been tried out on a large scale before. I had hoped that someone would have given it an extended trial before now, and I trust that Dr Theobald's interesting paper will lead to a real and thorough test.

I am, Sir, yours faithfully,

Isle of Anglesey June 11th

J J. MOIR

MOYNIHAN MEMORIAL

To the Editor of THE LANCET

SIR,—The board of the General Infirmary at Leeds realise that the greatest memorial to the genius and work of the late Lord Moynihan must always be advancement in the art of surgery which he did so much to promote. They feel, however that it is their duty and privilege to perpetuate a record of Lord Moynihan's work for surgery and his labours in and for the General Infirmary at Leeds by the erection within its walls of a suitable memorial. Already a ward has been named the Moynihan Ward, but much more than this is clearly required. The board have appointed a committee to submit and carry out a suitable scheme and on behalf of this committee I am able to state that the sum of £750 has already been received. More than this is needed if the memorial is to be adequate and I am authorised to invite subscriptions from medical and lay sympathisers. It is suggested that one guinea would be a suitable amount, though more or less would be very acceptable.

Subscriptions should be forwarded to the General Infirmary at Leeds in the name of the Moynihan Memorial Fund or to myself. They will all be very gratefully acknowledged.

I am Sir yours faithfully

CARLTON OLDFIELD

Chairman Moynihan Memorial Committee

June 14th.

BICENTENARY OF THE BRISTOL ROYAL INFIRMARY

To the Editor of THE LANCET

SIR,—Sunday next June 20th marks the completion of 200 years work at the Bristol Royal Infirmary: for on this day in 1737 the out-patient department was opened for the reception of patients. though the formal opening did not take place until December of that year. We feel that the bicentenary of the oldest provincial teaching hospital in the Kingdom is a matter of more than local interest and importance. To mark the occasion a carnival is being held at the Clifton Zoo from July 7th to 10th. The formal celebrations will take place later in the year probably early in October when it is hoped that former students and others associated with the infirmary will make a special effort to be present.

I am Sir yours faithfully

E. WATSON WILLIAMS

Hon Secretary Bicentenary Celebrations Committee

Clifton Bristol June 14th

THE LANCET 100 YEARS AGO

June 17th 1837 p 448

From an answer to a Correspondent

Corporal Ward.—Were it a necessary consequence of the inversion of images on the retina that the mind should perceive them to be upside down then it might be correct to speculate on the cause of their being recognised in an upright state. But the upside-down result has not yet been proved to be inevitable. Every theorist however appears to have forgotten this. Be the image pictured in whatever position it may on the retina, the mind clearly recognises the lower end to be the lowest and the upper to be the highest but why it does so it is an unnecessary to debate as the question how the mind comes to be sensible of the representation of an object exists on the retina at all. The opinion that the "change of flanks" is effected by the decussation of the optic nerves is not new but has often before been hazarded. Experiments and not conjectures are needed in physiology.

A NEW MENTAL HOSPITAL

ON Monday last Sir Kingsley Wood, the Minister of Health opened the new mental hospital at Runwell Essex which has been provided jointly by the county boroughs of East Ham and Southend-on-Sea. Erected at a cost of £650 000 it has been planned so as to combine all the previous advances in mental hospital design including a separate admission hospital four research laboratories a general library and a recreation hall equipped with gymnastic apparatus. There is also a new feature—a detached closed unit for disturbed cases.

Everything has been done with the aim of convincing both patients and public that nervous and mental disease must be treated with the same intensive care scientific means and human understanding as any physical disorder. With a site of 600 acres between Wickford and Rettendon (about 24 miles from East Ham and 12 from Southend) the buildings have been placed on a slight slope open to the south and sheltered by rising and well wooded ground on the north. They are widely spaced and in this way it is hoped that an atmosphere may be engendered of light and airy buildings without obtrusive restraint, and with a freedom from the institutional feeling. Wide verandahs with large solarium form a feature of the patients' units, and airy rooms with french windows enable them to feel that they are in a sanatorium rather than a great institution.

Occupational therapy is considered a very important part of the treatment to be provided and provision has been made for teaching many different handicrafts as well as upholstery printing tailoring boot-repairing metal work and carpentry. The admission hospital is built in a single storey and affords every facility for open air treatment. In this unit is the X-ray department the pathological and biochemical research laboratories a department of hydrotherapy and laboratories of experimental psychology and clinical pathology. Two detached villas at a distance from the other buildings, are for voluntary patients suffering from the milder forms of mental disorder; they allow of as much freedom and privacy as possible and they are described as the first of their kind in a public hospital. Units for quiet and employable patients are provided with large gardens and are connected by covered ways with the occupation therapy shops. There are also three parole units for patients not needing much supervision and able to enjoy more freedom both inside and outside the grounds. They have easy access to the kitchen garden laundry and farm where a certain number of the patients will be employed. Finally there is the closed unit situated well away from the other buildings accommodating 60 male and 100 female patients suffering from the more severe forms of mental disorder. This is planned to be unlike the old fashioned refractory block and will have a large garden.

The hospital has room for 1010 patients and forms a community of perhaps 1400 people with 25-30 separate units. The physician superintendent is Dr Rolf Ström Olsen the deputy superintendent Dr S. M. Coleman the senior physician Dr S. L. Lawt and the assistant physicians Dr M. B. Brody and Dr P. P. Haldane. There are also two resident house physicians. The visiting consultant staff are: Dr T. Rowland Hill Mr Podney Maingot Dr I. Vitenzon, Mr J. Lyle Cameron Dr H. L. Bonnell Mr C. G. Talbot Dr C. White Phillips and Mr W. Milton Bull. The architects of the new building are Messrs Fleck and Sutcliffe.

BRITISH ASSOCIATION OF RADIOLOGISTS

At a meeting of this association held at the British Institute of Radiology on June 11th and 12th, under the presidency of Prof J M WOODBURN MORISON, the Skinner lecture on the

After-care of Patients Suffering from Cancer of the Breast

was delivered by Dr F HERNAMAN JOHNSON. After drawing attention to the increase in the death-rate from carcinoma of the breast during the last thirty years, the speaker gave it as his opinion that little advantage was likely to accrue from the adoption of heavy dosage methods of radiation therapy in this field, and that radiation therapy should be employed primarily as a palliative measure following radical surgery. The objects to be attained in palliation were first to free the patient from any external signs of the growth, secondly to relieve pain and discomfort, thirdly to delay the onset of and, if necessary, treat metastases, and lastly to treat the patient from a psychological point of view. In this respect attention was drawn to the value of surgery where the patient was more likely to feel that the growth had in fact been completely removed. Reference was made to Dr A T Todd's work, but Dr Hernaman Johnson did not consider this suitable for hospital patients. Referring to biochemical tests he was of opinion that the differential sedimentation rate, while not of value in diagnosis, was useful in assessing the response to treatment. Isolated skin recurrences should, he thought, not be regarded as of grave importance, heavy dosage should be employed locally. Axillary recurrences should be removed surgically, while supraclavicular gland metastases should be dealt with by heavy doses of X ray therapy. Metastatic deposits in bones were worth while treating, and in such cases Todd's method should be employed. Thoracic invasion rarely responds and the prognosis with liver metastases should be regarded as quite hopeless.

Wave-length in Radiotherapy

Mr G F STEBBING, opening a discussion on wave length as a factor in radiotherapy, emphasised the fact that in this form of treatment results were obtained only when the dosage was carried to a level which produced a fairly severe reaction on the skin, and that all factors which might contribute to a lessening of this reaction were worthy of consideration. It was almost universally accepted that the same physical dosage measured in röntgens (r) produces less normal tissue damage when delivered by radiation of short wave length. Despite this lesser biological response of the normal tissues Mr Stebbing was of opinion that so far as malignant cells were concerned the reverse was the case and that using short wave length rays a more lethal effect on the tumour was obtained. This view was based primarily on the belief that the action of the radiation on the tumour cells is direct and not through the tumour bed. In addition to this "selective" action the use of short wave length rays as produced by higher voltages resulted in greater penetration and so an improved depth dose which, though numerically not of a high order, was in many cases of very great value. Thus an absolute gain of 5 per cent per field resulted in a total gain of 30 per cent if six ports of entry were employed as in many cross fire methods.

Dr DOUGLAS WEBSTER, on the other hand, while admitting that the use of higher voltages enabled a greater depth dose to be obtained, pointed out that a similar result could be obtained by the use of greater treatment distances. He did not consider that there was any selective or specific action in relation to wave length, and in support of this view he pointed out that from the physical point of view ionisation effects did not run parallel to the wave length of the radiation and that, from the practical aspect, the measurement of the r at the higher voltages was a matter of some difficulty. On the biological side he quoted a number of experiments in which the employment of radiation generated at widely different voltages had failed to produce any different response on the part of the biological medium. On clinical grounds there was, as yet, no concrete evidence to support the view that better results were obtained by the use of higher voltages and that clinics employing X rays generated at potentials of 600 kv had not produced results superior to those obtained at 200 kv.

Dr RALSTON PATERSON, supporting Dr Webster, was of opinion that short wave length rays were, as a rule, to be preferred since their use entailed less skin reaction for the same measured dosage. This advantage, however, he considered to be due not to any specific or selective action on malignant tissue but to some physical factor as yet undetermined and possibly related to a defect in our present measurement methods.

Dr STRUTHERS FULTON did not consider that radiation effects were due to any specific or selective action. Clinically similar and equally satisfactory results were obtained in skin malignancy by the use of long wave length X rays on the one hand and gamma rays on the other. The fact that with X rays these results were obtained at relatively lower dosage levels as measured physically in röntgens tended to support the view held by Dr Paterson that our present methods of measurement might, in time, require to be revised.

Dr R E ROBERTS, arguing against there being any selective action, pointed out that if long wave length rays produced a greater effect on the skin it was reasonable to assume that they would also produce a greater effect on tumour tissue.

Dr F ELLIS cited a number of clinical and biological experiments from the literature, all of which tended to show that no selective action in relation to wave length did in fact exist.

Mr STEBBING, replying, pointed out that skin tumours were, as a rule, sensitive, and that care must be exercised in drawing deductions from this material. With deep seated tumours the difficulty was greater and it was in the treatment of such cases that the value of short wave length rays was most apparent.

Low Voltage Near-distance X Ray Therapy

Dr S B ADAMS, after outlining the particular merits of this form of treatment, proceeded to describe two special applicators which had been devised at the Royal Cancer Hospital with a view to providing a more homogeneous distribution of energy on the skin surface than that obtainable with the standard applicators. He discussed the question of dosage, illustrating his remarks by slides of clinical subjects successfully treated by this method. Clinical and biological problems in relation to the factors of time and intensity were being investigated, but it was as yet too soon to put forward any definite results.

Dr J F BROMLEY considered the possibilities of the method in the treatment of lesions in the mouth and in carcinoma of the rectum. The particular merit of this method in the treatment of skin malignancy in the region of the eye was demonstrated by a series of slides showing clinical results. Dr Bromley also briefly outlined certain biological experiments on which he was engaged.

Prof MORISON emphasised the importance of considering the dosage at the tumour level. The profound effect which distance has in modifying this was graphically demonstrated as was, also the comparatively small gain in depth dose associated with the use of higher voltages. An interesting table was shown comparing from the point of view of energy output and distribution radiation from a radium bomb a radium applicator and an X ray tube operating at 200 kv and a short distance X ray tube operating at 60 kv. Prof Morison discussed the possible difference in biological response to split dosage, continuous and massive methods of treatment. During treatment the tissues gradually changed in their sensitivity to radiation. Tumours tended to become radio resistant and he was therefore experimenting with a method whereby the daily dose was gradually increased throughout the period of treatment.

Dr R McWHITTER thought that similar results could be obtained by the employment of a tube operating at the 200 kv level. He had further found the single day massive dose method quite satisfactory for the treatment of skin malignancy.

Dr FULTON was of opinion that the near distance X ray therapy plant provided something which could not be duplicated by any other apparatus at present available. While approximating in energy distribution to a radium plaque it gave a very much higher output. On the other hand a high voltage X ray tube while providing a high output, gave a more profound depth dose effect. Two points had to be borne in mind in using the short distance X ray tube. First the depth dose was small and for this reason he felt that it should be used with discretion in the treatment of tonsillar lesions and secondly, the energy distribution is such that it falls off rapidly towards the edge of the field. This fact must be borne in mind in treating skin malignancy and a correspondingly wider area be subjected to radiation. Short distance X ray therapy had taught us two important lessons. The first of these was that permissible dosage is closely associated with the size of the field irradiated and with small fields it was possible to administer doses measured in r similar to those given by radium. The second point was that dosage is also related to volume of tissue irradiated and here we find that as a result of the superficial distribution of energy in the tissues it is possible to deliver higher doses with the short distance X ray tube than with an X ray tube generating rays of much shorter wave length but operating at a greater distance and so irradiating a larger volume of tissue despite the fact that the ports of entry may be similar in size.

Ventriculography

Dr ERIC LYNNHOLM of Stockholm gave an address before a large audience on radiological experience in ventriculography based upon 800 ventriculograms examined by ventriculography and cephalography. The use of the method was he said increasing. In Stockholm air was now solely employed as the contrast agent; with refined technique it would show all the details which could be elicited by opaque

media the use of which had proved inseparable from risk. Arteriography was only employed when a vascular lesion was suspected. For radiography he used an apparatus whose constant focal distance at all angles enabled him to make a three-dimensional reconstruction of the ventricular system. When the reconstruction was superimposed upon an anatomical chart slight deformities were readily appreciated and the lesions could be accurately localised. He demonstrated his new type of grid constructed entirely of metal which absorbed its own secondary and tertiary radiation. The grid lines were so fine as to be almost invisible and the thickness could be adapted to varying conditions and objects. The ventriculographic appearance of supra tentorial tumours he divided into three groups, each with its characteristic picture:—

(1) *Concealed tumour* causing lateral displacement with tilting of the upper end of the septum pellucidum away from the tumour and flattening of the upper angle of the lateral ventricle of the same side. The higher the tumour the greater the amount of tilting of the septum.

(2) *Tumour situated laterally* at the level of the Sylvian fissure causing lateral displacement without tilting of the septum or indentation of the outer angle.

(3) *Temporal tumours* the typical picture was a lateral displacement with a characteristic angulation of the septum and third ventricle to one another. This angle was open towards the side of the tumour. The lateral ventricle on this side was narrowed, drawn out into a point inferiorly and showed an indentation on its lower outer side. In this group it was essential to observe the temporal horn. The direction in which it was displaced would determine whether the tumour was superficial or deep.

Filling of the third ventricle of the aqueduct and of the fourth ventricle was accomplished by special techniques. Characteristic filling defects were then observed with intrinsic and extrinsic tumours of the third ventricle. It was sometimes possible to determine the operability of intraventricular tumours by observing whether they were completely surrounded by air or attached to the ventricular wall. He demonstrated examples of very small cysts at the foramen of Monro—an important type of which he had seen four cases—tumours of the anterior middle and posterior parts of the third ventricle and pineal tumours. Posterior third ventricle tumours could not always be distinguished from one another. The pinealoma gave a well-defined filling defect with more or less complete filling of the supratentorial recess. Calcification in the tumour did not necessarily signify that it was a pinealoma. Four such tumours had proved to be gliomata and one a tuberculoma. Tumours of the lamina quadrigemina were often hard to distinguish from posterior tumours of the third ventricle; in some cases both regions were invaded. If the ventricular defect were small in comparison with the degree of displacement of the aqueduct the tumour was likely to be quadrigeminal. Careful observation of the aqueduct gave valuable indications. Quadrigeminal tumours displaced it towards the clivus but not laterally. Upper vermian tumours caused early compression of the aqueduct and in the lateral view have a typical picture—namely an angulation of the supratentorial part of the aqueduct, the peak of which was directed backwards, together with a bowing of its infratentorial part and of the fourth ventricle downwards and forwards unaccompanied by any lateral displacement. This deformity did not occur with inflammatory stenosis. Tumours of the cerebellar hemispheres caused bowing of the aqueduct towards the base with lateral displacement. They rarely obliterated

the cavity of the fourth ventricle. Tumours of the lower vermis pressed upon the lower part of the fourth ventricle which, together with the aqueduct, was dilated. Angulation of the aqueduct was rarely seen. Intraventricular tumours, if large, might completely obliterate the cavity of the fourth ventricle. If small, they could be outlined a rough or irregular outline indicated a papilloma. Ependymomata and medulloblastomata showed smooth surfaces.

Cerebellopontine angle tumours displaced the aqueduct dorsally and towards the opposite side, and often caused a depression of the lateral wall of the fourth ventricle. Pontine tumours also displaced the aqueduct dorsally, but lateral displacement did not occur. Dorsal displacement of the aqueduct with flattening of the floor of the fourth ventricle had been observed in a few cases of meningioma of the olivus.

Dr E. W. TWING, proposing a vote of thanks, stressed the personal element in Dr Lysholm's investigations. The brilliant results which he had demonstrated resulted from the concentration of the cases in one centre, and from the concentration of the best brains upon that material. Routine radio-

graphy could not obtain equivalent results. Every case involved careful and prolonged personal study.

Short Papers

Dr H. W. A. POST outlined the technique and normal and pathological salpingographic appearances in the uterus and tubes.

Dr E. ROHAN WILLIAMS indicated the value of urography, ascending and intravenous, in demonstrating the physiological dilatation of the renal pelvis and ureters in pregnancy, and the cystographic diagnosis of placenta prævia.

The use of lipiodol in the localisation of spinal tumours was described by Dr H. M. WORTH, who gave details of the technique and showed a number of cases diagnosed by lipiodol introduced by the lumbar and cistern puncture respectively.

Dr M. H. JURE read a paper on cases of suprarenal tumour, and described the clinical and radiological appearances in the Pepper and the Hutchinson types of neuroblastoma of the adrenal medulla. He drew attention to certain characteristic bone changes in the latter type.

PUBLIC HEALTH

Refresher Courses

THE life of a medical officer in any branch of the public health service is increasingly hard. The enlarging scope of the public health department is calling for a very high type of medical officer who requires, in addition to medical knowledge, personal and social qualities to which Sir Kingsley Wood alluded at the last annual dinner of the Society of M.O.H.s. The imagination of the advertising agent, the zeal of the missionary, the patience of Job, the hide of the hippopotamus were among the qualifications, "coupled," he added, "I suppose, with medical knowledge." On the same occasion Dr Ernest Ward spoke of the initiative taken by the Society in promoting higher education, and its hope for the advice and co-operation of the Ministry of Health in arranging for it. The organisation of short post graduate courses for the various classes of medical officers employed by local authorities was the first step suggested. No time has been lost and a circular now issued by the executive secretary of the Society to local authorities tells of provisional arrangements for a series of refresher courses. Three such courses are announced:

- (1) Sept. 28th to Oct. 1st, at Cardiff, for medical officers of health, limited to 40.
- (2) Week beginning Nov. 8th, at Manchester, for school medical officers, limited to 30.
- (3) Early in 1938, a course in infectious diseases, in London, limited to 20.

No sanction, it seems, is required for expenditure incurred on these courses by local authorities which have the conviction that they will get an adequate return for their money in the maintenance of efficiency on the part of their staff. The Board of Education has also expressed general agreement with the principle and a syllabus of a school medical course is now being drawn up. An attendance fee of two guineas will cover the central organising expenses and local fees for each course, and prompt application is desirable in view of the strict limitation of numbers. No other commendation of the scheme is necessary than a mild expression of surprise that it has not been put into execution before. All honour to the present initiative.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 5TH, 1937

Notifications—The following cases of infectious disease were notified during the week: Small pox, 0; scarlet fever, 1517; diphtheria, 925; enteric fever, 39; pneumonia (primary or influenzal), 652; puerperal fever, 38; puerperal pyrexia, 124; cerebro-spinal fever, 17; acute poliomyelitis, 3; acute polio-encephalitis, 1; encephalitis lethargica, 5; relapsing fever, 2 (Leatherhead, Wharfedale R.D.); continued fever, 1 (Stockport); dysentery, 33; ophthalmia neonatorum, 115. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on June 11th was 2902, which included: Scarlet fever, 736; diphtheria, 830; measles, 91; whooping-cough, 446; puerperal fever, 22; mothers (plus 13 babies), encephalitis lethargica, 282; poliomyelitis, 2. At St. Margaret's Hospital there were 24 babies (plus 13 mothers) with ophthalmia neonatorum.

Deaths—In 123 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 7 (0) from measles, 0 (0) from scarlet fever, 16 (0) from whooping-cough, 29 (4) from diphtheria, 46 (13) from diarrhoea and enteritis under two years, and 17 (4) from influenza. The figures in parentheses are those for London itself.

Four persons died at Birmingham of diphtheria and 2 each at Darlington and Worcester. There were 7 fatal cases of diarrhoea at Willesden and 4 at Leeds.

The number of stillbirths notified during the week was 313 (corresponding to a rate of 41 per 1000 total births), including 52 in London.

NEW HOSPITAL AT IVER—The new Iver, Denham and Langley Cottage Hospital will be opened on July 2nd by the Duke of Kent.

ROYAL EYE HOSPITAL, SOUTHWARK—This hospital is setting up a special committee to carry out research with a view to preventing injuries to the eyes. A museum of various devices intended to protect the eyes of industrial workers is being prepared and the committee is asking employers in South London to help in the campaign. Plans are being prepared for two additional wards and accommodation for extra nursing staff is to be provided. The cost of this which is the first part of the rebuilding scheme will be about £50,000.

PARLIAMENTARY INTELLIGENCE

THE HEALTH SERVICES

We have already summarised (p. 1430) some part of Sir Kingsley Wood's important statement on committee of supply on the health services. A few of his chief points remain to be noted. Advances he said, had been made in the treatment of child bed fever; the discovery that certain organic chemical compounds could reduce both the mortality from this disease and the incidence of complications had been of outstanding importance. The epidemic of enteric fever during the year at Bournemouth, Poole, and Christchurch illustrated once again the difficulty of ensuring a safe milk-supply otherwise than by pasteurisation where the milk was as in this case obtained from many sources and pooled before distribution. There had also been an increase in the proportion of mortality caused by some of the diseases whose prevalence was greatest among the older part of the population—that was he supposed a natural corollary of the decline in the great killing infectious diseases which used to take a heavy toll at all ages. The fixing of the date from which the new overcrowding provisions were to operate in particular areas was proceeding steadily; up to the end of March 1937 orders had been issued for fixing the appointed date leaving 52 to be fixed before the end of the year. The same date marked the end of the fourth year of the five-year programme of slum clearance. It had more than kept its promise. Four-fifths of that programme was represented by 106,000 houses and already the houses in submitted orders and purchase agreements exceeded that number. In April last he asked the maternity and child welfare authorities to review their arrangements for the supply of milk and meals to nursing and expectant mothers and young children. Replies from such places as Durham and Leyton had stated that their services were already complete; 33 authorities had reported that they were taking further action. During the past year he had urged on local authorities the importance of the fullest supervision over the health of children between the ages of 18 months and five years; at least 47 authorities had established special clinics for toddlers and 53 had arranged for the school medical services to be available for the younger children while 64 had appointed additional health visitors. He had been struck with the fact that although we had perhaps the finest social services in the world they were by no means fully utilised; he hoped in the autumn of this year in connexion with the Board of Education and the Central Council for Health Education to organise a national campaign to bring these health services more to the notice of the people. The keynote of the campaign would be *Use your health services*. They would get a real advance apart from the creation of new services in getting the people to utilise the services already in existence. The establishment of the Ministry of Health was the outward expression of Parliament that national health was of supreme and vital importance to the State and it was undoubtedly inspired by that new and wider humanity which was so prevalent to-day. Their aim must continue to be along those lines and it should be their desire to the best of their endeavour and capacity to make good health the birthright of every citizen. Certainly this could be said that the fight for good health could not be successfully conducted with a limited choice of weapons or on a narrow front. We must more than ever use the whole armoury which modern knowledge and medical science had given us and, if possible, broaden our front and deal not only with the specific diseases of the individual but more and more with the wider conditions—the environment, the occupations and the conditions of our people. Although there was much to accomplish it could be claimed that their efforts to build up a healthy nation had not been in vain.

CRITICISMS OF GOVERNMENT POLICY

Mr ADDON said that the block grant system limited the full play of the health services. He hoped that before it was too late the Minister would turn his mind to the planning of satellite towns and the location of industry otherwise when they had got over the immediate needs they would be faced with greater social problems and difficulties than in the past. The provision of public abattoirs was urgent.

Mr HAMILTON KERR said there was still little supervision of the child between the ages of two and five years. A definite health policy should ensure the regular medical supervision of every child up to the age of 16. In every local centre a properly organised file of the entire health history of each boy and girl should be readily available.

Mr LAKESHIRE contended that the necessity for a range of services which the Minister of Health controlled through local authority arose largely because of poverty and until poverty was dealt with we should not make true progress. Until children could get within their homes all the food necessary for them, we should not obtain that healthy virile youth population that we all wanted to see.

Sir FRANCIS FRIDLANDT dealt with the proposed additional ophthalmic benefits. There was he said a contest between the ophthalmic surgeon on the one hand and certain persons in the benefit societies on the other, as to what was the proper way of administering ophthalmic benefit. Obviously it was the most convenient thing to allow opticians to prescribe spectacles. But the departmental committee of 1922 had stated that an official register of opticians would tend to mislead the public into thinking that registered opticians were competent to discharge functions which belong only to those who have had a medical training. And the committee of 1927 said: "We are not satisfied that even those opticians who are most highly qualified in all other respects are sufficiently trained in this respect." Since 1927 the Association of Dispensing Opticians and the National Ophthalmic Treatment Board had been set up with inclusive charges well within the means of those whose family income did not exceed £260 per annum. That being so it was dangerous to allow additional benefit to be given by persons not qualified to find out the trouble at the back of the eye.

The case for satellite cities was agreed, but the difficulty was to get them put into effect by local authorities. It was not simply the establishment of a garden city here or there that was needed but the adaptation of the whole town planning movement in that direction. Meanwhile London was sprawling over the countryside. Some authority ought to take hold at once of the centres that were being made by the arterial roads. They would be the centres of the future communities and yet they were allowed to be taken up by petrol stations, breweries, public houses and caravans. He hoped the Greater London planning authority would be revived.

Sir FRANCIS went on to endorse a plea made by Mrs. Tate for a trial of the Scandinavian experiment in the treatment of venereal disease which had resulted in almost complete immunity from syphilis and a large reduction of other diseases. Here the position had been improved by the scheme of treatment centres but a large number of persons failed to pursue the treatment to the finish. Of the nearly 60,000 persons who last year attended V.D. clinics only 2,000 had the final tests of cure and nearly 20,000 ceased to attend before completion of their treatment. The first essential was education and the Ministry of Health ought to exercise pressure on the local authorities to keep up their quota of subscriptions to the Social Hygiene Council. They also had to consider seriously whether it was not

desirable to introduce some kind of compulsion either in notification or in ensuring completion of treatment. In Holland a voluntary system had given results better than ours, last year they had only 11 fresh infections per 100,000 of the population.

Mr J HENDERSON said that rheumatism was startlingly prevalent in large portions of industrial England. Several continental governments, backed up by the municipalities, had established a network of spas and clinics. In this country the leading hospitals were not dealing as they should with the manipulative treatment of this disease. He urged the Minister to organise a national service of municipal clinics in conjunction with the local hospitals.

Mr G GRIFFITHS urged the Minister to deal with burning pit heaps in mining districts, the fumes of which caused ill health. He commented on the absence in the report of anything about diabetes. We had in this country not fewer than 200,000 diabetics. A State insured person who was a diabetic got his insulin free, if the wife of such a person was a diabetic and was prescribed insulin, her husband had to pay anything from 10s to 18s a week for it.

Mr GODFREY NICHOLSON said that the Ministry were losing a sense of proportion with regard to maternal mortality. Too much stress was being put on antenatal treatment and not enough emphasis on the importance of skilled attention at the actual time of birth. An eminent gynaecologist had said to him that it was the specialist who should be looking after the actual confinement and the practitioner doing the antenatal care. The solution of the problems of maternal and infantile mortality lay in educating the whole population.

Miss WARD said that before embarking upon a campaign of "Use your health services" it was important to know whether there were adequate health services provided by every local authority. We should have a detailed survey of what health services were available to see whether local authorities were taking advantage of the powers which they could use, and whether they had the necessary finances to enable them to do so.

MINISTERIAL REPLY

Mr BERNAYS said that the figures in the latest annual report of the chief medical officer of the Board of Education were illuminating. They showed that out of 1,080,000 school-children examined, only 0.7 per cent were suffering from definitely bad nutrition and only 10.6 per cent from subnormal nutrition. There was also the encouraging fact—which gave the lie to the assertion about the deterioration of our national physique—that the general death-rate had fallen by one third during the last 25 years and that the death-rate from tuberculosis in children under one year of age had been reduced by a half in the same period. Malnutrition was a problem and the Government could legitimately claim that it had been tackled with energy and effect in the last few years. Reference had been made to the question of satellite towns. This question was dealt with by a departmental committee in 1924, which recommended the establishment of a National Planning Board. The main suggestion was that the larger local authorities should be encouraged, and, if necessary, compelled to make further outward development in the form of planned units outside the town, separated by adequate areas of open land. The instances of Welwyn and Letchworth garden cities had been cited, and the Government had been asked why we cannot apply experiments of that kind. These garden cities were started by public utility companies, and local authorities were doing much to secure the same objects. After all, town planning was planning to secure proper sanitary conditions, amenities, and conveniences. The increasing use of joint committees meant the extension of planning for larger units.

[Sir FRANCIS FREMANTLE: They are doing nothing to marry factories to residences, and that is the whole essence of the thing.]

Houses were being built, Mr Bernays rejoined under healthy conditions on the outskirts of the towns, and this policy would be continued and encouraged. With the existing organisations and working with the sympathy of established authorities, much was being and could be done.

Objection had been taken to the recognition of opticians as having power to prescribe for defective eyesight. While the Minister was satisfied that the ultimate ideal was that all persons should go to a medical eye specialist, he was satisfied that it would not be practical politics under present conditions to make this an invariable practice in all cases. The reasons were that the supply of qualified medical men was not sufficient to meet the needs of the whole population and that the people had not been educated up to recognising the advisability of this course in what they regarded as ordinary, straightforward cases of defective eyesight. The regulations, therefore, provided for either of the alternative courses being followed. Every insured person was required to visit his own insurance doctor before his application for ophthalmic treatment was granted.

PENSIONS FOR LOCAL GOVERNMENT OFFICERS

In the House of Commons on June 11th the Local Government (Superannuation) Bill was read a second time. In moving the second reading Sir KINGSLEY WOOD said that the main and general object of the Bill was to secure such a measure of uniformity as might reasonably be required in regard to the provisions to be made by local authorities for pensions for their staffs. It required provision to be made for the superannuation of all whole time local government officers and facilitated similar provisions by local authorities over and above that made by the general law relating to pensions for their other employees. The Bill brought the local government service in this respect into line with the long-established practice of the Civil Service and thus added another measure of protection in old age to a further section of the community. The present rate of contribution for both officers and servants was 5 per cent of their remuneration with an equivalent contribution from the local authority. It was estimated that in the present circumstances the rate of contribution needed to secure the benefits was in total 12 per cent for officers and 10 per cent as at present for servants, and the Bill accordingly proposed to increase the rate for new entrant officers by 1 per cent with a similar increase in the authorities' contribution. The Bill contemplated the minimum of interference with the various superannuation schemes established under local Acts, but if the main purpose was to be achieved it was essential that those schemes should be extended to cover, when they did not already do so, all whole-time officers.

DIFFERENTIAL TREATMENT

Captain ELLISTON expressed disappointment that no provision was made by the Bill for the optional grant of added years by local authorities in the case of their professional officers. He had been advocating that concession since 1922. He had some special experience of the conditions of service of medical officers. They were men who spent five or six years in acquiring their professional qualifications. At the end of that period if they were wise, or if they were fortunate, they took a period of service as house physician or surgeon in a hospital and then they had to acquire the further professional qualifications which would enable them to take a public health appointment. In view of the tremendously varied character and importance of public health work in these days, a medical officer who hoped to secure an appointment had to acquire special experience in a number of directions. He had to spend a period of residence in hospital, he had in most cases to spend a period in a tuberculosis sanatorium. He

had to acquire extra experience perhaps in diseases of women and children, and so on. That meant that he was usually 30 years of age or more before he could obtain his first appointment. Owing to this late entry at a higher salary level the contributions of these officers in relation to their pensions were much higher than those of non professional officers many of whom entered the local government service as soon as they left school. He (Captain Elliston) was hopeful that it was not too late for the Minister to consider whether he could make some concession in this matter and give local authorities the power if they so desired to add years, not exceeding ten to the number which professional officers in such circumstances as he had described had actually served. Alternatively it was being suggested that years spent in professional training should be allowed to count as service years within the meaning of the Act. He knew the anxiety of the Minister to promote co-operation between the municipal hospitals and the great voluntary hospitals. He (Captain Elliston) was told that there were members of the House of Commons who would like to see it made possible by this Bill to provide for the interchangeability between the federated superannuation scheme of the voluntary hospitals and the superannuation scheme of the local authorities. If that were practicable it would undoubtedly facilitate the interchange of personnel and would do a great deal to raise the standard of the hospital services in this country. What he had said also applied to other officers such as health visitors, nurses, and so on.

Mr W. H. GREEN said the London County Council had 3400 nurses on probationary service and he gathered that under this Bill those nurses would immediately be placed under the superannuation scheme. There was a great amount of coming and going in the ranks of probationers particularly in the nursing profession and a hardship would be imposed if all the probationary nurses to whom he had referred were compelled immediately to be placed under the superannuation scheme. Another point affected the health visitors engaged by local authorities. He was delighted to think that at long last the retiring age of health visitors was to be fixed at 60 but that carried with it a great grievance, because to qualify for the maximum pension health visitors must have put in 40 years service. That would be well nigh impossible under the conditions of the Bill. It was very seldom that a health visitor was appointed under the age of 25. That meant that at the most they could put in only 35 years service. He wondered whether some compensation might be provided in the Bill in regard to the 5 years service.

Sir FRANCIS FRIMANTLE said among civil servants they had men of the highest possible attainments. Those interested in local government wanted to get the same type of men into the local government service. To attract them to this service they must remove certain disadvantages one of which had been the absence of superannuation provision. This Bill helped to meet that difficulty. There were points in the Bill in which the transition from voluntary service to public service might be made more easy. The arrangements under the present Bill were not satisfactory for bringing in the midwives who while working under voluntary associations in villages where they were not employed for the whole of their time were also under a contract with the local authority under the Midwives Act to provide a midwifery service. Sir Francis asked the Minister to give the most earnest consideration to the requirements which would enable the midwives to secure the full advantages of superannuation. It was difficult to recruit midwives yet it was on the midwifery service that they depended very largely for the improvement of the maternity services of the country. He gave his cordial support to this Bill as a constructive measure for building up a great local government service.

MINISTERIAL REPLY

Mr BERNAYS Parliamentary Secretary to the Minister of Health said that the clause which dealt with the position of nurses was based on the recommendation of the Selby Bigge Committee. Obviously this was a matter which could very well be considered when the Bill reached committee. The Minister would be glad to receive any representations on the part of the interests concerned between now and the committee stage. As to the point raised by Captain Elliston as to why there was a differentiation in the rates of contribution between officers and servants, a uniform rate of 5 per cent was fixed by the Act of 1922 for all employees brought within its provisions. It was urged before the Selby Bigge Committee that the remuneration of an officer usually increased automatically or by promotion from the beginning to the end of his service and he was pensioned on the average remuneration of the last five years of his service when his remuneration was obviously at the highest. On the other hand a workman received wages which soon reached their maximum and remained at the same level for many years. Accordingly a workman's contribution paid throughout on a flat basis of remuneration brought into the superannuation fund a greater sum in relation to the pension drawn than did that of an officer. Since the same scale of pension was applicable to both classes of employees a smaller percentage rate of contribution should be sufficient in the case of a workman than in the case of an officer.

THE SCOTTISH MEASURE

On the previous day Mr ELLIOT Secretary for Scotland moved the second reading of the Local Government Superannuation (Scotland) Bill. He explained that there were two specific points in which the Bill differed from the English measure. In the first place it was proposed that the minimum number of officers to be covered by the scheme should be 50; under the English Bill the minimum number was 100. In the second place in the Scottish Bill they also made provision for local authorities to act jointly in cases where they had not themselves a sufficient number of employees to make a separate scheme. But all the small burghs had fewer than 50 whole-time officers so for this purpose they would be counted as employees of the county councils.

NOTES ON CURRENT TOPICS

Physical Training

In the House of Commons on June 11th the Physical Training and Recreation Bill was read a third time. On the motion for the third reading Mr LUDSAY Parliamentary Secretary to the Board of Education said that since the second reading action had been taken on four points. The local organisations committee had done a great deal of preliminary work and he hoped the local bodies would begin work during the summer holidays. The committee on propaganda intended to start an intensive campaign in the autumn. It had given special consideration to the use of films. The technical committee had been considering the question of the National College and had proceeded a long way. The question of research was very important. The grants committee could begin to consider applications as soon as the statutory powers were obtained. The aim was to build up a new leadership of trained men and women and to inspire the whole nation with the great ideal of personal fitness. They could not rest content until every child in the country had equality of access to all that was meant by physical education and had an equal chance to become a healthy citizen.

Mr LUDSAY said he had come to the conclusion that the part of the Bill which ultimately would probably prove the most valuable would be that which dealt with physical education particularly in the form of remedial exercises for those whose work was deleterious to their health rather than that

desirable to introduce some kind of compulsion either in notification or in ensuring completion of treatment. In Holland a voluntary system had given results better than ours, last year they had only 11 fresh infections per 100,000 of the population.

Mr J HENDERSON said that rheumatism was startlingly prevalent in large portions of industrial England. Several continental governments, backed up by the municipalities, had established a network of spas and clinics. In this country the leading hospitals were not dealing as they should with the manipulative treatment of this disease. He urged the Minister to organise a national service of municipal clinics in conjunction with the local hospitals.

Mr G GRIFFITHS urged the Minister to deal with burning pit heaps in mining districts, the fumes of which caused ill health. He commented on the absence in the report of anything about diabetes. We had in this country not fewer than 200,000 diabetics. A State-insured person who was a diabetic got his insulin free, if the wife of such a person was a diabetic and was prescribed insulin, her husband had to pay anything from 10s to 18s a week for it.

Mr GODFREY NICHOLSON said that the Ministry were losing a sense of proportion with regard to maternal mortality. Too much stress was being put on antenatal treatment and not enough emphasis on the importance of skilled attention at the actual time of birth. An eminent gynaecologist had said to him that it was the specialist who should be looking after the actual confinement and the practitioner doing the antenatal care. The solution of the problems of maternal and infantile mortality lay in educating the whole population.

Miss WARD said that before embarking upon a campaign of "Use your health services" it was important to know whether there were adequate health services provided by every local authority. We should have a detailed survey of what health services were available to see whether local authorities were taking advantage of the powers which they could use, and whether they had the necessary finances to enable them to do so.

MINISTERIAL REPLY

Mr BERNAYS said that the figures in the latest annual report of the chief medical officer of the Board of Education were illuminating. They showed that out of 1,630,000 school children examined only 0.7 per cent were suffering from definitely bad nutrition and only 10.6 per cent from subnormal nutrition. There was also the encouraging fact—which gave the lie to the assertion about the deterioration of our national physique—that the general death-rate had fallen by one third during the last 25 years and that the death-rate from tuberculosis in children under one year of age had been reduced by a half in the same period. Malnutrition was a problem and the Government could legitimately claim that it had been tackled with energy and effect in the last few years. Reference had been made to the question of satellite towns. This question was dealt with by a departmental committee in 1924, which recommended the establishment of a National Planning Board. The main suggestion was that the larger local authorities should be encouraged, and, if necessary, compelled, to make further outward development in the form of planned units outside the town, separated by adequate areas of open land. The instances of Welwyn and Letchworth garden cities had been raised, and the Government had been asked why we cannot apply experiments of that kind. These garden cities were started by public utility companies, and local authorities were doing much to secure the same objects. After all, town planning was planning to secure proper sanitary conditions, amenities and conveniences. The increasing use of joint committees meant the extension of planning for larger units.

[Sir FRANCIS FREMANTLE: They are doing nothing to marry factories to residences, and that is the whole essence of the thing.]

Houses were being built, Mr Bernays rejoined, under healthy conditions on the outskirts of the towns, and this policy would be continued and encouraged. With the existing organisations and working with the sympathy of established authorities, much was being and could be done.

Objection had been taken to the recognition of opticians as having power to prescribe for defective eyesight. While the Minister was satisfied that the ultimate ideal was that all persons should go to a medical eye specialist, he was satisfied that it would not be practical politics under present conditions to make this an invariable practice in all cases. The reasons were that the supply of qualified medical men was not sufficient to meet the needs of the whole population and that the people had not been educated up to recognising the advisability of this course in what they regarded as ordinary, straightforward cases of defective eyesight. The regulations, therefore, provided for either of the alternative courses being followed. Every insured person was required to visit his own insurance doctor before his application for ophthalmic treatment was granted.

PENSIONS FOR LOCAL GOVERNMENT OFFICERS

In the House of Commons on June 11th the Local Government (Superannuation) Bill was read a second time. In moving the second reading Sir KINSELEY WOOD said that the main and general object of the Bill was to secure such a measure of uniformity as might reasonably be required in regard to the provisions to be made by local authorities for pensions for their staffs. It required provision to be made for the superannuation of all whole-time local government officers and facilitated similar provisions by local authorities over and above that made by the general law relating to pensions for their other employees. The Bill brought the local government service in this respect into line with the long-established practice of the Civil Service and thus added another measure of protection in old age to a further section of the community. The present rate of contribution for both officers and servants was 5 per cent of their remuneration with an equivalent contribution from the local authority. It was estimated that in the present circumstances the rate of contribution needed to secure the benefits was in total 12 per cent for officers and 10 per cent as at present for servants, and the Bill accordingly proposed to increase the rate for new entrant officers by 1 per cent with a similar increase in the authorities' contribution. The Bill contemplated the minimum of interference with the various superannuation schemes established under local Acts, but if the main purpose was to be achieved it was essential that those schemes should be extended to cover, when they did not already do so, all whole-time officers.

DIFFERENTIAL TREATMENT

Captain ELLISTON expressed disappointment that no provision was made by the Bill for the optional grant of added years by local authorities in the case of their professional officers. He had been advocating that concession since 1922. He had some special experience of the conditions of service of medical officers. They were men who spent five or six years in acquiring their professional qualifications. At the end of that period if they were wise, or if they were fortunate, they took a period of service as house physician or surgeon in a hospital and then they had to acquire the further professional qualifications which would enable them to take a public health appointment. In view of the tremendously varied character and importance of public health work in these days, a medical officer who hoped to secure an appointment had to acquire special experience in a number of directions. He had to spend a period of residence in hospital, he had in most cases to spend a period in a tuberculosis sanatorium. He

Sir FRANCIS FREMANTLE said among civil servants they had men of the highest possible attainments. Those interested in local government wanted to get the same type of men into the local government service. To attract them to this service they must remove certain disadvantages, one of which had been the absence of superannuation provision. This Bill helped to meet that difficulty. There were points in the Bill in which the transition from voluntary service to public service might be made more easy. The arrangements under the present Bill were not satisfactory for bringing in the midwives who while working under voluntary associations in villages where they were not employed for the whole of their time were also under the Midwives Act to provide the local authority under the Midwives Act to provide a midwifery service. Sir Francis asked the Minister to give the most earnest consideration to the requirements which would enable the midwives to secure the full advantages of superannuation. It was difficult to recruit midwives yet it was on the midwifery service that they depended very largely for the improvement of the maternity services of the country. He gave his cordial support to this Bill as a constructive measure for building up a great local government service.

Mr. LAFY-SMITH said he had come to the conclusion that the part of the Bill which ultimately would probably prove the most valuable would be that which dealt with physical education particularly in the form of a medical exercise for those whose work was deleterious to their health rather than that

which dealt with physical recreation. It must not be taken for granted that because young medical men engaged in active physical recreation up to the age of 25 or so they did not need physical education. One of the most striking observations which had fallen from Lord Dawson of Penn was that when he had watched hikers, tennis players, and even territorialists he had noted that many of them were suffering from defects of posture, stooping shoulders, and bad chests, which would pay them out a little later when the health and strength of youth had passed. He (Mr Lees-Smith) had never envied great athletes from the point of view of permanent fitness for life. When he read of the death of great athletes and noted their age he came to the conclusion that they were not quite as well off as the rest of the population and he was reminded of an observation by Plato that "an athlete is on a slippery edge in respect of health." He hoped it would not be thought, therefore, that by providing facilities for great athletic prowess they would be doing the work of building up the physical health of the nation.

Mr WAKEFIELD said speaking for himself, and he was sure also for his colleagues on the National Advisory Council, their aim was to try to make the great mass of the people, young and old, physically fit. They did not want to get a few sprinters doing 100 yards in 10 seconds, they would far rather have a million people doing 100 yards in 12 or 13 seconds. The result of their work would not depend on the success and ability of one or two outstanding athletes but on the general excellence attained by all.

Mr LINDSAY, replying to the debate, said that while they all wished to encourage the games which were characteristic of this country there was a great deal to be said for physical education as such. He was told by experts that at the present time they were all going about half dead, and that there were a few very simple exercises which every member of the House of Commons could take every day and which would make a great difference to the health, the physique, and the happiness of those who engaged in them. They did not quarrel with that theory at all. He had the greatest admiration for what was being done in Germany, Czechoslovakia, Sweden, Denmark, and elsewhere, but he was still convinced that they had to proceed on the basis of our characteristic British games. If they did that he was quite certain they would make this organisation a complete success.

School Medicine

On June 14th in committee of supply, Mr KENNETH LINDSAY, Parliamentary Secretary to the Board of Education, said that the total increase in the vote over last year was for £1,296,233. Part of the increase was due to general maintenance charges, and there was another item, provision for physical training under the Government's new scheme. That provision would be made in a supplementary estimate. During the last 18 months provision had been made for the youngest children by way of 7500 nursery schools in 80 different areas. Fifty new schools with playing fields attached were approved in 1935-36, and during the last year 90 such new schools were also approved. During the last two years, 111 playing fields had been acquired for separate schools, and 61 to cater for a variety of schools had been acquired. Gymnasiums had been provided for 117 elementary schools. Mr Lindsay was glad to be able to report progress along many lines of advance in regard to the School medical service and physical education. Since the recent circular was issued 34 new proposals and 5 proposals for enlarging existing nursery schools had been received. The present position was that 89 nursery schools were recognised by the Board of Education and in addition 31 had been approved in principle and 10 were under consideration. While the growth was rapid in proportion the total was still comparatively small and there were still many areas where local conditions would justify providing these schools

but where proposals had not been received. Their object was to obtain for all children under five years of age whose home conditions were unsatisfactory light airy rooms, special playgrounds, play material, and a happy environment which they needed for normal physical and mental development.

MORE STAFF NEEDED

The school medical service was a wonderful service, but it needed more staff. Since the recent circular was issued 32 authorities had increased their staff by the appointment of six whole time and 29 part-time medical officers, 12 authorities had appointed aural and 8 ophthalmic specialists, and one a specialist on rheumatism. One hundred proposals had been received for building school clinics and extending old ones and there were 18 new schemes for orthopaedics, 19 for aural treatment, and 15 for artificial light treatment. These were examples of how the staff was being increased, but there was still leeway to make up. At the time of the issue of the circular it was estimated that there were less than two-thirds of the number of school dentists required. He was glad to say, however, that 61 authorities had increased their staff by employing 62 full time and 23 part time dentists. But the ideal they must achieve was an annual inspection of all school children, otherwise he did not see how they could make good progress in this which was probably one of the most important aspects of the health services. There were also day open-air schools, residential schools for delicate children, and the problem of the feeble minded was always with them. It was particularly difficult to deal with in the countryside. For some children the only solution was the residential school and on that score one new proposal had been received from a country district.

On June 11th in the House of Commons the Children and Young Persons Bill, which has already passed through the House of Lords, was read a second time.

QUESTION TIME

WEDNESDAY, JUNE 9TH

Milk Ration for Boys in the Navy

Mr GRAHAM WHITE asked the First Lord of the Admiralty the present amount of the milk ration for boys in the Navy.—Mr DUFF COOPER replied: There is no fixed ration of milk for boys in the Navy as they are victualled under the general mess system and are provided with a varied dietary without fixed rations of the various items of foodstuffs. The average amount of milk issued daily to each boy is estimated to be approximately $\frac{1}{2}$ pint.

Colonel GRATTON: Will my right hon. friend say whether the milk is fresh or tinned?—No further answer was given.

Industrial Employment of Children at Home

Mr DENMAN asked the Home Secretary whether his attention had been called to the charges made of excessive employment of children at home on industrial work, whether he could give any information as to the extent of this practice, and what steps he was taking to stop it.—Mr GEOFFREY LLOYD, Under Secretary, Home Office, replied: I am obliged to my hon. friend for calling attention to this matter, about which no complaints have reached the Home Office. In 1931 as the result of an inquiry it was reported by the education authorities that 652 boys and girls aged 12-14 were employed in industrial work at home within the limits allowed by the law. My right hon. friend is proposing to ask the education authorities in the near future for information as to the application of the law as amended by the Children and Young Persons Act 1933, and this information will include the point now raised.

Royal Marines and Tuberculosis

Mr ROBERT TAYLOR asked the First Lord of the Admiralty the number of Royal Marines invalided out of the service owing to tuberculosis, the number who

had applied for pension; and the number of cases in which pensions were awarded during the last three years.—Mr DORR COOPER replied: During the period of three years ended April 30th 1937 65 Royal Marines were invalided out of the service on account of tuberculosis of which number 62 were pulmonary and 3 other forms; each invalid was automatically considered for an award of pension which was granted in 43 cases.

THURSDAY JUNE 10TH

Health of Spanish Refugee Children

Mr LEACH asked the Minister of Health whether the Basque children who recently reached this country had been vaccinated and inoculated before their arrival and if so against what diseases were they vaccinated or inoculated and when were these operations performed.—Sir KINGSLEY WOOD replied: So far as I am aware no special measures of vaccination or inoculation were taken before the children's arrival in this country, but approximately 60 per cent were found on examination to have been vaccinated against small pox. I understand that a first inoculation against typhoid has now been given to nearly all the children in the camp at North Stoneham.

Sir ANCHBALD SOUTHEY asked the Minister of Health how many Spanish refugee children had been admitted into this country and how many cases of typhoid or suspected typhoid had occurred amongst them.—Sir KINGSLEY WOOD replied: According to the information with which I have been supplied 3881 children arrived at the camp at North Stoneham on May 23rd and 24th. Six cases of typhoid including one not finally diagnosed and one of paratyphoid have occurred amongst them. Three children are at present under observation for this disease.

Sir A. SOUTHEY: In view of the risk of the spread of this disease would the right hon. gentleman give an assurance that none of these children will be allowed to move to other parts of the country until they have undergone the full quarantine?—Miss WILKINSON: Is it not a fact that the arrangements in regard to quarantine have been most admirably carried out by the voluntary service of doctors?

Sir KINGSLEY WOOD: The responsibility for the conduct of this matter rests with the voluntary committee. I think that everyone will agree that my department have given all the advice and assistance that can be given in this matter and we shall continue to do so. So far as the question of the removal of children is concerned I am anxious myself, subject to satisfactory medical conditions that these children shall leave the camp as soon as reasonably practicable and possible. Any assistance that my medical officers can give to medical officers in districts where they may have to go in order to secure safety so far as health is concerned will be given.

Sir J. LAMB: Will the medical officers of health be informed before the arrangements are made to transfer these children?

Sir KINGSLEY WOOD: Oh yes Sir. It is obviously a very important responsibility on the local medical officers of health.

Sir JOHN LAMB: Does the right hon. gentleman realise that some of these children have already been removed from the camp and that some of them are in my own constituency? Have the necessary steps been taken between the Ministry of Health and the local authorities to make sure that the children are fit to be removed?

Sir KINGSLEY WOOD: The matter is one for the local authority in the area and the medical officer concerned. From my own knowledge and observation I believe that the medical officers in the districts are fully alive to the need for properly carrying out their duties.

Juveniles and National Health Insurance

Mr THORNTON asked the Minister of Health whether the court of inquiry had come to any settlement in connexion with the fees to be charged by the doctors when boys and girls become employed after leaving school; and whether the Government intend bringing in a Bill to deal with the matter.—Sir KINGSLEY WOOD replied: Yes Sir. The court of inquiry, which was asked to consider the doctors' capitation fee to be paid as from January

next for all insured persons entitled to medical benefit on the assumption that employed juveniles would then be included has reported in favour of the present rate of 9s per annum. I shall introduce the necessary Bill as soon as Parliamentary business permits.—Mr THORNTON: Is it in consequence of their powerful organization that the doctors have got all that they wanted?—Sir KINGSLEY WOOD: I would advise the hon. gentleman to consult the doctors.

Health Insurance and Ophthalmic Treatment

Sir ERNEST GRAHAM LITTLE asked the Minister of Health whether the National Ophthalmic Treatment Board was taken into consultation by him in drafting the Additional Benefits Amendment 1937 and whether he was satisfied that the arrangements made by these regulations for permitting sight testing by recognised opticians would in no way interfere with the development of the best possible ophthalmic medical service in this country.—Sir KINGSLEY WOOD replied: Before the regulations to which the hon. Member refers were made the fullest consideration was given to the views expressed on behalf of doctors associated with the work of the National Ophthalmic Treatment Board. I see no reason why any arrangements made under the regulations should interfere with the development of a satisfactory ophthalmic medical service.

Major PROCTOR asked the Minister of Health whether in connexion with the Additional Benefits Amendment Regulations, 1937 he could say what steps had been taken by him to obtain agreement between the sight-testing opticians and the National Ophthalmic Treatment Board with regard to the question of sight testing in connexion with ophthalmic benefit.—Sir KINGSLEY WOOD replied: Repeated attempts have been made to obtain agreement between the different schools of thought on the subject referred to by my hon. and gallant friend and I have myself received representative deputations from both sides. Unfortunately it was not possible for any agreement to be arrived at.

Unemployed Persons and Dental Treatment

Mr WHITFIELD asked the Minister of Health whether his attention had been drawn to the increased cost of public assistance committees due to dental treatment and the provision of artificial dentures to persons in receipt of allowances from the Unemployment Assistance Board; and whether he was prepared to arrange for such cost to be met by the Board and thus relieve the local public assistance committees of what should be a national charge.—Sir KINGSLEY WOOD replied: I have received a communication from one local authority on this matter. I am advised that under the Unemployment Assistance Act the Board have no power to defray the cost of dental treatment.—Mr WHITFIELD: Do I understand that the public assistance committees will still have to bear the burden of these additional costs?—Sir KINGSLEY WOOD: Yes Sir; the provision of medical benefits remains the responsibility of the local authorities under the Act.

MONDAY JUNE 14TH

Spanish Refugee Children

Mr MITCHELL asked the Home Secretary whether he could make any statement in regard to the future of the Spanish refugee children in Great Britain in the event of it being impossible to repatriate them in the near future.—Mr LLOYD Under-Secretary Home Office replied: The committee responsible for the care and maintenance of these children has given an undertaking to the Government that they will be repatriated by the committee as soon as circumstances permit. It is clearly impossible to foretell when circumstances will permit of repatriation. As my right hon. friend the Minister of Health stated on June 10th the responsibility for any arrangements for moving them from the camp at North Stoneham rests with the voluntary committee which I understand making arrangements for their accommodation in groups in private institutions and similar places.

Effect of Noise on Health

Sir RALPH GLYN asked the Minister of Health whether he would appoint a committee to inquire into the detrimental effect of unnecessary noise on the health of people

living in large cities, and how far medical opinion supported the view that many instances of nervous breakdowns, &c., were due to causes which could be to a great extent eliminated—Sir KINGSLEY WOOD replied Research into the effects of noise on workers carried out by the Industrial Health Research Board of the Medical Research Council, on which reports have been published, shows that it is very difficult to detect and measure any specific effects of noise on health, and it is hardly possible to assess within the limits of a Parliamentary answer the influence which medical opinion would assign to the part played by noise in the increased strain of modern life I will send my hon. and gallant friend some references to medical publications on this subject As at present advised, I do not think the subject lends itself to investigation by a committee as suggested.

TUESDAY, JUNE 15TH

Nurses' Hours in Scottish Mental Hospitals

Mr ROBERT GIBSON asked the Secretary of State for Scotland what was the total number of attendants and nurses on the staffs of, or employed at, mental institutions in Scotland as at May 31st, 1937, how many of these individuals had a tour of duty extending to 84 or more hours, 78 and under 84 hours, 72 and under 78 hours, 66 and under 72 hours, 60 and under 66 hours, 54 and under 60 hours, 48 and under 54 hours, 42 and under 48 hours, and under 42 hours per week, respectively, what were the corresponding figures for the Smithston institution in Greenock, and if he had any statement to make regarding the introduction of legislation to restrict the working week of such individuals to a maximum of 48 hours—Mr WEDDERBURN, Under Secretary of State for Scotland, replied The information desired is not immediately available but steps have been taken to obtain it and I will communicate with the hon. and learned Member when it is received.

Maternal Mortality

Mr JAMES GRIFFITHS asked the Minister of Health the maternal mortality rate for each of the administrative counties and county boroughs in Wales for the year 1936, and the corresponding rate for England and Wales as a whole—Sir KINGSLEY WOOD replied The following table gives the information requested by the hon. Member—

	Maternal mortality deaths for 1936 per 1000 total (live and still) births	
	Puerperal sopsis	Other puer- peral causes
England and Wales	1 34	2 31
Cardiff C B	2 55	1 13
Merthyr Tydfil C B	1 02	—
Newport C B	0 50	1 77
Swansea C B	2 22	4 44
Administrative Counties		
Anglesey	1 30	5 20
Brecknock	1 25	4 99
Caernarvon	2 38	4 17
Cardigan	1 48	7 42
Cardmarthen	1 54	5 01
Denbigh	0 83	2 91
Flint	2 04	3 58
Glamorgan	2 42	2 92
Merioneth	—	1 82
Monmouth	2 96	3 52
Montgomery	—	1 43
Pembroke	2 25	1 50
Radnor	—	3 07

Housing Conditions in Scotland

Sir THOMAS MOORE asked the Secretary of State for Scotland whether, in view of the fact that over 250,000 houses were still required to replace unfit dwellings in Scotland and that, owing to the present condition of the building trade, it would not be possible to erect more than some 25,000 houses per annum, he could state what special steps he proposed to take to encourage temporary reconstruction and reconditioning in order to improve the present position—Mr WEDDERBURN replied In view of the present pressure on the supply of building trade

labour in Scotland, my right hon. friend is not satisfied on the information at present before him that a policy of temporary reconstruction and reconditioning would make any material contribution to housing needs but following representations made to him by the Convention of Royal Burghs he is making further inquiries on the subject.

Hospital Staff at Gibraltar

Lieut. Commander FLETCHER asked the Secretary of State for War whether the normal hospital staff at Gibraltar was too small to be able to cope with 30 unexpected patients, or whether there were other reasons, and, if so, of what nature, for the dispatch of four nurses to Gibraltar to nurse the wounded from the *Deutschland*—Mr HORE BELISHA replied The staff of the Military Hospital, Gibraltar, is adequate to deal with a normal number of patients. The casualties from the *Deutschland* were abnormal.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr A. G. Lee to *Pembroke* for R.N.B.
Surg. Lt. Comdr T. G. B. Crawford to be Surg. Comdr.
Surg. Lt. Comdr V. J. Fielding retires at own request.
Surg. Lt. Comdr R. V. Jones to *Wellington*.
Surg. Lts G. L. Hardman, J. F. Meynell, W. S. Parker, and W. B. Teasey to *Victory* for R.N.B. and I. C. Macdonald to *Falmouth*.

ROYAL NAVAL VOLUNTEER RESERVE

Proby Surg. Lt. D. R. Matland to be Surg. Lt.

ARMY MEDICAL SERVICES

Col. J. Heatly Spencer, C.B.E., late R.A.M.C., having attained the age for retirement, is placed on ret. pay.
Lt. Col. W. H. O'Riordan, M.C., from R.A.M.C., to be Col.

Royal Army Medical College Lt. Col. and Bt. Col. R. C. Priest, K.H.P., R.A.M.C., to be Professor of Tropical Medicine and Consulting Physician to the Army.

ROYAL ARMY MEDICAL CORPS

Maj. G. S. McConkey to be Lt. Col.

TERRITORIAL ARMY

Capt. W. C. Armstrong to be Maj.
Lts G. O. Brooks, F. G. Matland, W. B. R. Monteith and J. B. Bishop to be Capt.
R. M. McGregor (late Offr. Cadet, Edinburgh Univ. Contgt. (Med. Unit) Sen. Div., O.T.C.) to be Lt.

ROYAL AIR FORCE

Flight Lt. H. C. S. Pimblett is promoted to the rank of Squadron Leader.
Flying Offrs. promoted to the rank of Flight Lt. J. R. R. Jenkins, L. W. R. Farley, and R. C. O'Grady.
Flight Lt. T. J. M. Gregg to No. 4 Flying Training School, Abu Sueir, Egypt.
Dental Branch—B. Blackburne to Medical Training Depot, Halton, on appointment to a non-permanent commission as a Flying Offr. for three years on the active list.

AUXILIARY AIR FORCE

No. 600 (City of London) (Fighter) Squadron J. H. Attwood is granted a commission as Flying Offr.

INDIAN MEDICAL SERVICE

The Commander in Chief in India has notified the following appointments—

Col. W. J. Powell, C.I.E., as Assistant Director of Medical Services, Peshawar District, with effect from March 27th last.

Col. W. L. Watson O.B.E. as A.D.M.S. Kohat District.
Lt. Col. H. C. D. Rankin, O.B.E., as specialist in medicine, Deccan District.

Appts. made in India—

A.D.M.S. Col. T. C. C. Leslie, O.B.E., Brit. Serv.
D.A.D.M.S. Maj. R. Murphy, R.A.M.C.

(Continued at foot of opposite page)

University of Oxford

Dr. Gardner was educated at Oxford University and St. Thomas's Hospital graduating in 1911. In the following year he was admitted to the fellowship of the Royal College of Surgeons of England and a year later he took his M.D. degree. From 1914 to 1917 he held a Radcliffe travelling fellowship and in 1923 he was awarded the prize for medical research. Dr. Gardner held the posts of demonstrator in medical anatomy at St. Thomas's Hospital and St. George's Hospital. He is a fellow of University College, Oxford, and the author of "Bacteriology for Medical Students and Practitioners" and of "Microbes and Ultramicrobes". He contributed the section on the dysentery group of bacilli to the Medical Research Council's "System of Bacteriology" in 1926. His work on the growth of *Shigella* has much to recommend it, and he is credited the cough-throw method of early diagnosis which he described in our columns in 1923.

University of Cambridge

On June 11th the following degrees were conferred —
 M.D.—F W Shepherd, T R Thomson and E. W. Taylor
 M.B. BChir.—J G Lewis, N B Rette and Guy Rigby
 Jones, S C Buck, G E Lorton A F W Harley A J Moon
 J. C. Culvercraft J H Water and F S Gorman
 M.B. M.F. Mackenzie M. F. Tattersall, J S Ellis,
 A L Jackson, H B Mellowes J M Scott E F W Grellier and
 K W B. Rogerson

At a meeting of the council of the college held on June 10th with Sir Cuthbert Wallace the president in the chair a letter was read from the Rockefeller Foundation presenting the sum of £500 for one year towards research work at the college. The honorary college medal was awarded to Sir Frank Colver in recognition of his many contributions to scientific odontology and to the service of the college. Sir Holburn Waring who has been a member of the council since 1913 and who was president of the college from 1935-36 presented a silver cup to mark his retirement from the council.

Diplomas of fellowship were granted to the following —

J. H. Mulvaney, M.R.C.P. Lond., King's Coll.; D. E. Fernandez, M.R.C.P. Lond., Ceylon and St. Barr's; J. H. Barnett, M.R.C.P. Lond., Univ. Coll. of Guy's; G. G. Ganger, M.R.C.P. Lond., Univ. Coll. of Guy's; M. B. Land, King's Coll. and West London; A. H. Charles, M.B. Camb., St. George's and St. Thomas; A. B. Evans, M.B. Camb., Westminster and St. Thomas; Ashton Miller, M.B. Camb., St. George's and St. Thomas; W. H. Crubellier, M.R.C.P. Lond., St. H. Lamb; G. F. Critchley, M.B. Lond., St. Thomas and Guy's; S. G. Mayer, L.R.C.P. Lond., London Hosp.; Guy Blackburn, M.B. Camb., St. Bart.; V. A. Law, M.B. Camb., London Hosp.; D. N. Rhina, M.B. Lucknow, Middlesex and London Hosp.; H. Hied, D. M., Guy's; J. C. Loe, M.B. Camb., St. Thomas's; W. R. Moringstam, M.B. Lond. Univ. Coll.; E. L. Williams, M.B. Camb., St. Thomas; K. G. F. Mackenzie, L.R.C.P. Lond., Cambrilree and St. Thomas; Amarnath, M.R.C.P. Lond., Calcutta, Middlesex and St. Bart.; R. T. L. Nayyar, M.B. Calcutta, Hosp. and St. Bart.; A. H. H. Talwar, M.B. Bombay, St. Bart.; R. A. Hughes, M.B. Liverpool; D. N. D. Rao, M.B. Bombay; T. H. Ackland, M.B. Camb., St. Bart.; S. Campbell, M.D. Belg. London Hosp.; G. N. Cooper, M.D. Oxon, Guy's; V. S. London; K. N. Chinn, M.B. Belg. St. Thomas and London Hosp.

Barmed, Sir D. W. Williams and Sir D. H. Pater
Diploma in Public Health.—Part I: Major-General H. J. M.
Perry. Part II: Dr Charles Lyster.

Diploma in Tropical Medicine and Hygiene—Major-General
W. J. MacArthur and Dr. Hamilton Katcher

Diploma in Ophthalmic Medicine and Surgery—Part I
Mr Leighton Davies and Mr Amcock Greaves, Part II: Mr

Diploma in Psychological Medicine—Prof F. L. Golla

Diploma in Laryngology and O'logy—Part I: Mr. F. J. Scott and Mr. Edward Carew Shaw Part II: Mr. T. J. Lorton

Diploma in Medical Radiology—Part I: Dr H T Hunt
Part II: Dr Hugh Davies

Diploma in Anæsthetics—Dr H F Gaikin Boyle
Diploma in Child Health—Dr A G Maitland-Jones

University of Wales

At recent examinations the following candidates were successful in obtaining the tuberculosis diseases diploma —

A. A. Azeez, M. P. Crowe, B. A. Dormer, M. C. Malkani, C. F. McConn, K. P. R. Philal, N. N. Sen, H. K. Surveyor, G. R. Talwalker and Helen Turner

University of Sheffield

Dr Gilbert Forbes has been appointed lecturer in forensic medicine and Dr J. M. Kennedy lecturer in infectious diseases. Dr J. Webster Bride has been appointed examiner in obstetrics for the final M.B. examination in September.

Middlesex Hospital Medical School

On Wednesday, July 21st at the Scala Theatre, Lord Dawson will distribute the prizes gained during the past year by students of this school. Dr G. E. Beaumont will deliver an introductory address entitled *The Breath of Life*. The wards of the hospital, the medical school and research departments, and the nurses' home will be open to inspection after the prize giving.

Queen's Hospital for Children, Hackney

This hospital is undertaking an extension and reconstruction scheme which will cost £50,000. Of this £30,000 must still be raised if the buildings are to be opened free of debt.

National Smoke Abatement Society

The offices of this society are being transferred from Manchester to London, and after Thursday, June 24th, the address to which all communications should be sent will be Chandos House, 64, Buckingham gate, Westminster, S.W. 1. The society's present London address at 71, Eccleston-square will no longer be used except where the personal attention of Sir Lawrence Chubb is desired.

Forthcoming Congresses

Meetings which have been arranged for the future include the following —

June	19th-23rd	Journées Médicales de Bruxelles	Brussels
	21st-25th	Silicosis Symposium	Saranac Lake N.Y.
"	26th-30th	Journées Médicales Internationales de Paris	Paris
July	1st-3rd	National Association for the Prevention of Tuberculosis	Bristol
"	5th-11th	International Hospital Congress	Paris
"	8th-10th	Oxford Ophthalmological Congress	Oxford
"	12th-17th	International Short wave Congress	Vienna
"	19th-24th	International Congress on Mental Hygiene	Paris
"	20th-24th	British Medical Association	Belfast
Aug	24th-1st	International Congress of Child Psychiatry	Paris
July	20th-1st	Population Congrès	Paris
Aug	5th-7th	Internationale Gesellschaft für Geographische Pathologie	Stockholm
Sept	29th-4th	International Swiss Medical Week	Interlaken
Sept	1st-8th	British Association	Nottingham
"	5th-9th	International Union Against Tuberculosis	Lisbon
"	13th-17th	International Congress of Radiology	Chicago
"	13th-15th	International Society of Gastro-enterology	Paris
"	16th-18th	International Congress on Hepatic Insufficiency	Vichy
"	27th-30th	International Child Welfare Congress	Rome
Oct	2nd-4th	International Congress for Psychotherapeutics	Copenhagen
"	4th-9th	International Rheumatism Congress	Paris
"	17th-22nd	International Society of Medical Hydrology	Wiesbaden and Frankfurt
Dec	8th-15th	International Congress of Ophthalmology	Calro
1938			
March	21st	International Leprosy Conference	Calro
"	26th-31st	International Congress on Rheumatism and Medical Hydrology	Oxford
September		International Surgical Society	Vienna

Newbury District Hospital

This institution has been remodelled and extended at a cost of some £24,000 and the new buildings were opened lately by Mr A. Thomas Lloyd, His Majesty's Lieutenant of Berkshire. Two wings have been added to form new men's and women's wards and the accommodation has been increased from 36 to 64 beds.

A National Dental Service

Sir Kingsley Wood, the Minister of Health, accompanied by Mr R. H. Bernays, parliamentary secretary to the Ministry, on Tuesday last received a deputation representing the British Dental Association, the Incorporated Dental Society, and the Public Dental Service Association. The deputation emphasised the need for a comprehensive dental service, as an essential sequel to the school dental service, which would provide dental inspection and treatment for every insured person. This could only be made possible by means of a statutory dental benefit. The service should be organised on a panel system similar to that in force for medical benefit, and the dentists, like the insurance medical practitioners, should be remunerated on a capitation basis. Sir Kingsley Wood said in reply that over 10 million persons—two thirds of the whole insured population of England and Wales—were already entitled to dental treatment as an additional benefit and that the scope of the existing scheme would be considerably extended by the new proposals for bringing juveniles into National Health Insurance. It was clear that the cost of providing dental benefit as a statutory benefit would be very heavy and would raise the question of an increase in the contributions paid by insured persons and their employers. He was nevertheless much impressed by the arguments put forward and promised to give them careful consideration.

Harveian Society of London

At the Buckston Browne dinner held at the Connaught Rooms on June 10th, Lord Hewart proposed the toast of the Society and said he thought doctors had little to fear from the Recording Angel. Dr A. H. Douthwaite, responding as president, announced that despite a doubling of its subscription the Society now had over 400 members. Its present stability would have been impossible but for the ten years' devoted work of Dr de Bec Turtle, whose latest benefaction was the gift of a cigarette box and snuffbox in celebration of Coronation year, while the dinner itself was one of the many manifestations of the generosity of Sir Buckston Browne. Mr M. F. Nicholls having ingeniously proposed the Guests, Mr H. L. Eason was led from thoughts of Harvey and the circulation of the blood to speculations about other circulations—of the port of the press, and of London traffic this last being sadly impaired by arterio-sclerosis, ischaemia, and clots in all the main arteries, with an occasional coronary thrombosis near the Bank of England. The next speaker, appropriately enough, was Mr Ernest Bevin, whose feelings about the bus strike caused him to appeal for closer relations between medicine and industry. He wished that doctors would take less interest in incidence and more in causation—that they would act as a look-out brigade and not postpone action until disease had killed a large number of people. The new chemical and machine age, coming so suddenly, had produced a situation in which all must co-operate to find a remedy. There was a growing desire to bring discovery and practice closer together, and nowhere was this more necessary than in medicine. The greatest sufferers from the gap were the working people: they paid a very large proportion of their income for medical service and were not quite getting value for money. There was not yet the right organisation for getting the right results, the service, with its long waits at institutions and its failure to include women and children was not organised for the present generation. What I resent more than anything else, said Mr Bevin, is the discrimination between those with one salary and those with another. Why a man should be classed as proletariat at £5 a week and as lower middle class at £5 1s passes my comprehension.

Mr Derek Curtis Bennett in the final speech of the evening spoke of what everybody owed—"not only in pounds, shillings and pence"—to the medical profession.

Dr Christopher Addison on whom a peerage was conferred in the Coronation Honours, has taken the title of Baron Addison of Stallingborough in the county of Lincoln

Salvation Army Mothers Hospital

Lady Baldwin, on June 8th opened a new isolation block at this hospital in Lower Clapton road. The block cost £8785

Disposal of the Dead

The sixth joint conference of the National Association of Cemetery and Crematorium Superintendents and the Federation of Cremation Authorities in Great Britain will be held at Torquay from June 28th to July 1st

West London Hospital

Prince Arthur of Connaught presided at the annual meeting of subscribers of this hospital and stated that 4411 in patients were received last year. Maintenance alone amounted to £65 300. The new buildings are to be officially opened by Queen Mary on Oct. 18th and will be named the Silver Jubilee extensions

St Thomas's Hostel for Babies Kennington

On June 7th Princess Helena Victoria opened the new nurses home attached to this institution. She also received purses towards the £6,000 which is the cost of the building

Lady Tata Memorial Grants and Scholarships

The trustees of this fund have awarded scholarships for research in blood diseases with special reference to leukaemia to Dr Jørgen Bloel (Aarhus Denmark) and Dr Edoardo Storti (Pavia, Italy). They have also awarded grants for research expenses or for scientific assistance to the following: Dr Julius Engelbreth Holm (Copenhagen), Prof Karl Järnval (Budapest), Prof James McIntosh (London), Prof Charles Oberling (Paris), Prof Eugene Opie and Dr Jacob Furth (New York), Dr Georg Weitzmann (Leipzig) and Dr Lucy Wills (London)

British Association of Radiologists

After holding its first annual general meeting at Birmingham in 1935 and its second at Manchester in 1936 this association came to London for its third annual meeting which was held on June 11th and 12th at the Reid Knox Hall, Welbeck-street under the presidency of Prof J. M. Woodburn Morrison. The discussions are largely reported on an earlier page. On the evening of the 11th some ninety members and their friends dined together at the Hotel Splendide Piccadilly, the diagnostic and the therapeutic groups were both well represented. In proposing The Association Mr S. J. Worsley acting principal of London University spoke of its aim to combine the conservative outlook of medicine with a quick adaptation to new ideas. London University he said still had the only chair of radiology in this country and its diploma of medical radiology was now a going concern, some eight of the London school being prepared to take part in preparing for it. Dr R. M. Beath who will preside next year when the Association meets in Belfast paid a tribute to the previous occupants of the presidential chair who had done so much to improve the education and status of the radiologist. He mentioned the decision to establish a higher diploma and an intention some time to found a college of radiology. Dr R. L. Roberts (Liverpool) proposed "The Guests" mentioning Miss Skinner who had generously endowed a lectureship. Sir Cuthbert Wallace who was president of a college on whose regulations for the fellowship the Association had moulded its own, and Dr Lyschols of Stockholm who was not only the fountain head of radiology in Sweden but also an expert yachtsman and engineer. Sir Walter Langdon Brown, in replying suggested possible mottoes for the Association amongst them (1) What shadows we pursue (2) For now we see it rough a plain darkly. The President concluded by giving as an extra toast "Absent Friends" with a special message to Mr Thurstan Holland prevented by his health from attending. Other guests present were Mr. Rock Carling and Mr. Dickson Wright

Appointments

- BAKER, ALFRED H. M.D. Bell., F.R.C.S. Eng. Temporary Assistant Surgeon to the Elizabeth Garrett Anderson Hospital
- BRUCHAMP, GUY M.B. Birm. Hon. Physician to the Charterhouse Rheumatism Clinic London
- BURGE, H. M.D. Lond., F.R.C.S. Eng. Resident Surgical Officer at King George Hospital, Ilford
- COOPER, H. G. N., B.M. Oxon. F.R.C.S. Eng. Resident Surgical Officer at the Ancoats Hospital, Manchester

WEDNESDAY—12 noon clinical and pathological conference (medical) 2 P.M. Mr F. J. King Ph.D. Carbohydrate Metabolism and Diabetes 3 P.M. clinical and pathological conference (surgical)

THURSDAY—2.15 P.M. Dr Duncan White Radiological Demonstration 3 P.M. operative obstetrics

FRIDAY—3 P.M. clinical and pathological conference (obstetrics and gynaecology)

Daily 10 A.M. to 4 P.M. medical clinics surgical clinics and operations obstetrical and gynaecological clinics and operations

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION 1 Wimpole street, W.

MONDAY June 21st to SATURDAY June 26th—WEST END HOSPITAL FOR NERVOUS DISEASES Welbeck street W. Afternoon M.R.C.P. course in neurology—CHelsea Hospital for Women, Arthur-street S.W. All-day course in gynaecology—LONDON CHEST HOSPITAL, Victoria Park Wed and Fri 6 P.M. M.R.C.P. course in heart and lung diseases—Brompton Hospital, S.W. Twice weekly 4 P.M. M.R.C.P. course in chest diseases Open only to members of the fellowship

HOSPITAL FOR EPILEPSY AND PARALYSIS Maida Vale W.

THURSDAY June 24th—3 P.M. Dr Blake Pritchard Demonstration

ST MARY'S HOSPITAL W.

TUESDAY June 22nd—5 P.M. (Institute of Pathology and Research) Dr W. E. Gye Recent Work on Cancer

HOSPITAL FOR SICK CHILDREN Great Ormond-street W.C.

THURSDAY June 24th—2 P.M. Mr Eric Lloyd Spinal Deformities in Children 3 P.M. Dr A. Signy Interpretation of Faecal Bacteriology

Out patient clinics daily at 10 A.M. and ward visits at 2 P.M.
 SOUTH WEST LONDON POST GRADUATE ASSOCIATION
 WEDNESDAY June 23rd—12.30 P.M. Visit to Parks, Davis and Co Hounslow

NOTES, COMMENTS, AND ABSTRACTS

KIPLING AND DOCTORS*

By VICTOR BONNEY M.S.

No writer has depicted the technical and spiritual aspects of medicine so understandingly as Rudyard Kipling and therein medical men are in debt to him for ever. Unlike the problems of other callings those presented to the doctor concerned as they are with the shifting phenomena of life are contained in no fixed framework of laws whereby they may be measured and solved, so that for an outsider to conceive and don the mental response to them requires not only great imagination but profound observation and thought as well. Kipling's understanding is assignable firstly to that insatiable craving for inner knowledge which was so striking a part of his nature and which compelled him to observe minutely and study the details of every sort of work and secondly to his power of vision which perceived in all work a spiritual significance far greater than the work itself. He himself has described to us how in his earlier days he was by force of circumstances introduced into intimate relation with men of many varied callings

"and in that Club and elsewhere I met none but picked men at their definite work—Civilians Army Education Canals, Forestry Engineering Irrigation Railways Doctors and Lawyers, and each talking his own shop. It follows then that the show of technical knowledge for which I was blamed later came to me from the horse's mouth—even to boredom.

But medicine had I think a special attraction for Kipling probably because its subtle problems challenged his deeply inquiring mind. In *Something of Myself* two doctors have specific mention. Dr Conland the best friend I made in New England, and the late Sir John Bland Sutton with whom as readers of the biography will remember Kipling pursued an unwilling cock to verify the workings of its gizzard. Bland Sutton was a very remarkable person avid for the acquirement of knowledge especially if the knowledge concerned matters odd and unthought-of and he was moreover gifted with the faculty of viewing things from an angle quite different from that used by the ordinary man. He possessed in short the very type of mind to interest and attract a mind like Kipling's and an old-standing and intimate friendship subsisted between them. He is introduced as Sir James Belton into the story *The Tender Achilles*.

"In the few precisely articulated words one could see Sir James himself—his likeness in face and carriage to the hawk-headed Egyptian god the mobile pursed lips and the stillness of the wonderful hand at his side.

The portrait is quite unmistakable to those who knew this famous surgeon. The St. Peppercott's of the tale is the Middlesex Hospital to which Bland Sutton gave a fully equipped pathological institute. His bust stands in the museum which forms a part of it and underneath the bust is this epitaph written by Kipling:

Adapted from a paper read before the Kipling Society on June 13th 1937

JOHN BLAND SUTTON

A SEEKER AFTER KNOWLEDGE THAT SHOULD
AVERT OR MITIGATE PAIN

*Labouring throughout life to this end
he gave greatly of his substance that
the search should continue in this place.*

His Knowledge of Medicine

Evidences of Kipling's knowledge of the technical side of medicine are numerous. For instance from *The Spies March* which deals with medical men in relation to infectious disease, take the following verse:

"Go where his pickets hide—
Unmask the shape they take
Whether a gnat by the waterside
Or a stinging fly in the brake
Or filth of the crowded street
Or a sick rat limping by
Or a smear of spittle dried in the heat
That is the work of a spy!

In *'A Deathbed'* the last two lines of the first verse accurately describe the outward signs of malignant disease of the throat or tongue

"This is a gland at the back of the jaw—
And an answering lump by the collar bone

Witness his reference to bacteriology in *'A Trans-lation'*.

Some cultivate in broth impure
The clients of our body—these
Increasing without Venus' cure
or cause disease"

In *Marklake Witcher* one of the characters is René Lannec, the French physician who by his invention of the stethoscope laid the foundation of our knowledge of diseases of the heart and lungs. René in the story is a prisoner of war on parole and Philadelphia tells Dan and Una how she watched René demonstrating his little wooden trumpet to Jerry the local seller of charms and cures. Jerry listening to René's chest says:

But unless I vo a buzzin in my ears Mosheur Lanark you make much about the same kind of noises as ol' Gaffer Macdon, but not quite so loud as young Copper—It sounds like breakers on a reef a long way off. Com' prunny! "Perfectly replies René I drive on the breakers. But before I strike I shall save hundreds, thousands millions perhaps, by my little trumpets.

The earliest stethoscopes were made of wood and I were shaped like a short trumpet. Jerry's picturesque simile exactly describes tubular breathing and how fine is René's reply!

But the fullest example of the accuracy of his medical knowledge is to be found in *The Ballad of Boh Da Thono*—I can remember

Boh Da Thono was a warrior bold;
His sword and his rifle were boomed with gold
And the Peacock Banner his helmet bore
Was stiff with bullion but softer with gore
He shot at the strong and he slashed at the weak
From the Salween scrub to the Chindwin creek
He crucified noble he sacrificed mean
He filled old ladies with keroseene!

He is pursued by Captain O'Neil of the Black Tyrone:

And his was a company seventy strong
Who hustled that dissolute chief along.

By Robert Bell Library

U. S. S. Medical College

O'Neil and his men eventually overtake him

"And at last they came when the Daystar tired,
To a camp deserted—a village fired,
A black cross blistered the morning gold,
But the body upon it was stark and cold
The wind of the dawn went merrily past,
The high grass bowed her plumes to the blast
And out of the grass on a sudden broke
A spurtle of fire, a whorl of smoke—
And Captain O'Neil of the Black Tyrone
Was blessed with a slug in the ulna bone—
The gift of his enemy Boh Da Thone "

Now mark Kipling's medical knowledge

"Now a slug that is hammered from telegraph wire
Is a thorn in the flesh and a rankling fire "

The wound suppurates as it would be sure to do

"The shot-wound festered—as shot-wounds may
In a steaming barrack at Mandalay
The left arm throbbed and the Captain swore
'I'd like to be after the Boh once more !' "

Septic fever supervenes and he becomes delirious

"The fever held him—the Captain said
'I'd give a hundred to look at his head !' "

Babu Harendra hears him and hankers for the rupees but is too cowardly to attempt to earn them. The Captain is invalided, goes to a hill station and takes him a wife

"And she was a damsel of delicate mould,
With hair of sunshine and heart of gold,
And little she knew the arms that embraced
Had cloven a man from the brow to the waist
And little she knew that the loving lips
Had ordered a quivering life's eclipse,
Or the eye that lit at her lightest breath
Had glared unawed in the Gates of Death
For these be matters a man would hide,
As a general rule from an innocent bride "

Meantime Babu Harendra is wending his way in the rearmost cart of the Government bullock tram when the Boh and his followers attack the convoy. There is a fierce fight with the escort

"But Fate had ordained that the Boh should start
On a lone hand raid on the rearmost cart,
And out of that cart, with a bellow of woe
The Babu fell—flat on top of the Boh !

For years had Harendra served the State,
To the growth of his purse and the grith of his *pét*
There were twenty stone, as the tally man knows,
On the broad of the chest of this best of Bohs
And twenty stone from a height discharged
Are bad for a Boh with a spleen enlarged
Oh ! short was the struggle,—severe was the shock—
He dropped like a bullock—he lay like a block,
And the Babu above him, convulsed with fear,
Heard the labouring life breath hissed out in his ear "

Repeated attacks of malaria cause great enlargement of the spleen, and a large proportion of the natives of malarial districts are so affected. Thus is a perfect picture of extensive rupture of the spleen with severe internal hemorrhage causing rapid death. Harendra then hacks off the head of the Boh, and sends it in a packing case to O'Neil with the finest example of a Babu's letter ever rendered into verse asking for the rupees. The case arrives at breakfast time

"Their breakfast was stopped while the screwjack and hammer
Tore wax cloth, split teak wood, and chipped out the dammer,
Open eyed, open mouthed on the napery's snow,
With a crash and a thud rolled—the Head of the Boh !

O'Neil's wife who is with child four months (this is very cleverly expressed) is terribly shocked and faints. From time immemorial it has been believed that impressions strongly stamped on the mind of a pregnant woman may imprint a physical simulacrum on the child, and at intervals cases are reported in the medical journals lending colour to the belief, as for instance, when a woman frightened by a one armed man brings forth a child with congenital absence of an arm. In this instance the child is born with a superficial birth mark, or congenital naevus, on its shoulder, resembling the contour of the Boh's head.

"And this is a fiction ? No, go to Simoorie
And look at their baby, a twelve month old Hour
A pert little Irish-eyed Kathleen Mavourneen—
She's always about on the Mall of a mornin'—
And you'll see, if her right shoulder strap is displaced,
Thus *Gules* upon *Argent*, a Boh's head, *erased* ! "

As in heraldry "*gules*" means red and "*argent*" white, the description of the red birth mark against the child's white skin is very apt. The term "*erased*" is also used in heraldry where an object, such as a head, is separated from the body it belongs to leaving a jagged edge, and the Boh's head *was* so separated. But Kipling also intended the word to be interpreted in a second sense. At the time the poem was written these birth marks were usually treated by obliterating or *erasing* them by electrolysis, and because the position of this one would render it specially unsightly electrolysis would have been almost surely carried out. It is a good example of Kipling's genius for playing on the double meaning of a word and blending the parallels special to two apparently unrelated subjects.

His Conception of the Doctor's Duty

The dominant force that lies behind medical work is often ascribed to conscious benevolence, whereas it is something quite different. Medicine disciplines its followers—not by order or drill as a regiment disciplines its men, but by the power of its traditional aims. The result, however, is the same—an automatic habit of thought and action which continues to work long after conscience and courage have gone by the board, and the doctor who struggles out of his sick bed to see a patient far less ill than himself, or from an island shieling to the boat bound for the mainland, carries in his arms a case of typhus, or allows a mosquito known to be infected with yellow fever to bite him, in order that the disease may be further studied, is embarrassed when his deed is lauded on the score of humanity and courage. He knows that its mainspring is a habit of duty, so long engrained, that it has become subconscious. Thus and the nature of the experiences through which the doctor's mentality is attained were well known to Kipling, as the following unpublished verse shows

"Such as in Ships and brittle Barks
Into the Seas descend,
They see the glories of the Lord
And wonders without end
But such as heal the sick and maimed,
Do meet more manifold
Amazements, in one midnight watch,
Than all the oceans hold "

You will observe that he quotes the first two lines from a previous poem of his.

In 1908 he delivered an address to the students of the Middlesex Hospital which in eloquence and understanding is by far the finest appreciation of the medical profession ever written, and almost every

sentence of it might be used as a text on which to found a dissertation. He described doctors as

"Your permanently mobilized army which is always in action always under fire against Death and whose business is

"to make the best terms you can with Death on our behalf to see how his attacks can best be delayed or diverted and when he insists on driving the attack home to take care that he does it according to the rules of civilized warfare

The same conception of the doctor's function recurs in the following unpublished verse written I believe many years afterwards

"Jan dies too soon, beside his work half planned
His days are counted and reprieve is vain.
Who shall entreat with Death to stay his hand;
Or cloke the shameful nakedness of pain?

The last line is very wonderful. The speech went on to recite the obligations of the profession

"In all times of flood fire famine plague pestilence battle murder or sudden death it will be required of you that you report for duty at once

and then its privileges

"If you fly a yellow flag over a centre of population you can turn it into a desert. If you choose to fly a Red Cross flag over a desert you can turn it into a centre of population towards which as I have seen men will crawl on hands and knees

You must remember that the South African War was only six years distant. He ended thus

"I do not think I need stretch your patience by talking to you about the high ideals and lofty ethics of a profession which exacts from its followers the largest responsibility and the highest death rate—for its practitioners—of any profession in the world. If you will let me I will wish you in your future what all men desire—enough work to do and strength enough to do the work

What finer wish could be uttered to an audience of young men?

Of all doctors those who devote themselves to research are I think the highest type for not only are the rewards small, but years of strenuous thought and labour may be expended only to find that the path followed to seek for knowledge leads nowhere or comes to a blind end. Kipling has voiced this as only he could voice it—these are the lines, unpublished as yet

"Send here the bold the seekers of the way—
The passionless the unshakable of soul
Who serve the inmost mysteries of man's clay
And ask no more than leave to make them whole

The interest Kipling took in medicine covered not only its present but its past and its future. In *Our Fathers of Old* he sings of the ancient physician astrologers:

"Yet when the sickness was sore in the land
And neither planets nor herbs availed
They took their lives in their lancet hand
And oh what a wonderful war they waged!
None too learned but nobly bold
Into the fight went our fathers of old"

These held that the universe and all it contains is one in ultimate essence and that happenings in the whole are reflected in the individual man who forms a part of it. In the address that he gave to the Royal Society of Medicine in 1928 he dwelt on this doctrine and looking into the future said

"It is then arguable that we may still mistake secondary causes for primary ones, and attribute to instant and visible agents of disease unconditioned activities which

in truth depend on some breath drawn from the motion of the universe—the entire universe revolving as one body (or dynamo if you choose) through infinite but occupied space? The idea is wildly absurd? Quite true. But what does that matter if any fraction of an idea helps towards mastering even one combination in the great time locks of Life and Death?"

In the labyrinth of knowledge through which we thread our way science has already unlocked many doors, but a myriad remain through which we must pass and who shall assert where or where not we may come to at last?—No doctor

OVERFEEDING AND PROTEIN METABOLISM

A GROUP of workers at the institute of physiology of Glasgow University have recently recorded the results of experiments designed to throw light on two important points—the effects of overfeeding on metabolism and the relative values to human adults and young people of the proteins of boiled and raw milk.¹

In 1904 Chittenden of Yale startled physiologists with his *Physiological Economy in Nutrition*, in which he maintained that the 15–18 grammes of nitrogen or 100 g of protein considered by Voit and other early workers to be a minimum daily requirement was in fact very much more than was needed for the repair of waste tissues, and that the excess, although the non-nitrogenous part was available for energy requirements, mainly passed from organ to organ or from tissue to tissue on the way to elimination and we can fancy that liver and kidneys must at times rebel at the excessive labour they are called upon to perform.

The method of experiment adopted in Glasgow by Dr. Guthbertson and his six fellow subjects who varied in age from 19 to 35 and in weight from 68 to 87 kg (under 0 to 14 st.) was to reach a stable output of urinary nitrogen on a self-selected basal diet of white and brown bread, 100 g of fresh butter cheese 500 ml raw milk, apple jelly, and raw apples. The water intake was kept constant. Some subjects received lettuce and tomato in addition. The daily protein intake varied from 0.82 to 1.21 g per kg of body weight, and the calories supplied from 34 to 62 per kg. A stable condition having been reached the excess ration was superimposed. It consisted of either 1000 ml of raw or boiled milk or in a further series beef lactose and butter with water this being dissimilar from the milk supplement only in the nature of the protein. An attempt to use a soya preparation as source of extra protein was closed after five days because of difficulty in consuming it.

All seven subjects showed a large retention of both nitrogen and sulphur after taking the extra food. The difference between raw and boiled milk was not significant either after a one-day surfeit or after a surfeit prolonged for eight days (two subjects only). Subject 5, in the longer experiment, showed decreasing retention as the experiment progressed. As he was 35 years of age he may be presumed to have finished growing but his younger companion who was only 19 seems to have made permanent use of the extra protein. A substantial but less retention of nitrogen was observed with beef and with the soya bean preparation. It is worth noting that the calcium retention was for raw or boiled milk only about 6 per cent. of the excess ingested and the authors point out that their experiments have no reference to the general merits of raw and boiled milk, but only to the relative retention of protein from them.

Further experiments were directed to making clear the relative protein-saving effect of fat and carbohydrate. It is obvious that the thermodynamic and work-output requirements of the body can only be

¹ Guthbertson, D. P., McCutcheon, A., and Munro, H. N. (1937) *Biochem. J.* 31, 851. Guthbertson and Munro 1942, p. 691.

met by the provision of combustible material. Fats, carbohydrates, and proteins will all burn, and there is some ground for the view that intake of protein might be reduced to that required for repair of wear and tear in the body or that amounts above this might be retained for future use, if either fat or carbohydrates were supplied in greater amount than is required to maintain body-weight. Apparently the only work showing the relative effect of addition of fat and carbohydrate to an apparently adequate diet is that of Voit in 1890. The present authors find that the effect of carbohydrate in sparing already metabolised protein is about half as much again as that of fat, but it seems that fat was more readily acceptable.

These investigations carried out on and by human subjects who chose and thrived on a basal diet on which they reached equilibrium are of greater value to the dietitian than similar experiments on the lower animals which have to make the best of what they can get and whose nervous systems are less affected by fads or idiosyncrasies. The diets chosen are hardly typical of the food of people—certainly not of medical students—in these islands and the subjects were few. The only exercise they took was short and fairly uniform walks which may partly account for the rather low diet which satisfied them. Allowing these criticisms, the important fact is established that the human system can, when circumstances permit of a rather fuller meal than usual, store for future use some of the extra "goodness" taken in. Further, if one cannot afford extra first-class protein one may do well to take extra fat and carbohydrates, in fact, a lot can be done by eating bread and butter. The stored nitrogen may be distributed over the body, but Outhbertson and his collaborators incline to think that much of it is kept in the liver.

AN ADJUSTABLE BED CUSHION

THE Dunlop Rubber Co., Ltd (Cambridge street, Manchester), now make an adjustable bed-cushion from their Dunlopillo material. It is shaped like a thick wedge but can be bent in the middle so that

BOLSTER

LEG REST

the thicker end of the wedge is doubled in thickness. The accompanying drawings show the cushions used as a bolster (opened out flat) and as a head-rest or leg-rest (one half folded laterally on the other). Dunlopillo cushioning is firm but soft as a support and is described as porous, self ventilating, moth-proof, and dustless. The bed-cushion is 3 feet wide (unfolded).

HOLIDAYS FOR WORKING WOMEN

THE following letter reaches us from the Women's Holiday Fund: "May we once more appeal to those now enjoying all the delights a holiday brings, on behalf of the working women of London living in crowded homes and noisy streets, among dingy surroundings? A short respite from monotonous drudgery and the struggle to carry on in the face of almost overwhelming odds would bring fresh courage and health to many a tired and harassed wife and mother. But the so much needed holiday is beyond her reach even though at times the longing 'to get right away' becomes unbearable. The narrow margin of money for the necessities of life in thousands of poor homes does not allow of such a luxury as a fortnight's holiday. Even by dint of saving a small sum weekly the cost is beyond the means of most

Last year through the help of the Fund which was founded 42 years ago, 1400 women obtained seaside holidays—over 700 took with them babies or small children (under 5 years of age). The society has now two homes of its own for mothers and babies at St Leonard's and Littlehampton, and in addition makes use of other suitable seaside homes and lodgings. The society is making every effort not only to maintain its existing work but to extend it. An urgent appeal is therefore made for donations (however small), so that a still larger number of weary women may have the refreshment of a holiday by the sea. Two pounds will pay for a mother and baby for two weeks."

The appeal is signed by the Bishop of London, the Dowager Countess of Leven and Melville, Sir George Blacker, The Rev. Father Devas, The Rev. J. Scott Lidgett, and Mrs. Alfred Loder, chairman of the executive committee. Donations should be sent to Miss Cooper, Denison House, Vauxhall Bridge-road, S.W.1.

A REVISED LIBRARY CLASSIFICATION

THOSE who regard the international decimal classification as inadequate for medical libraries, and yet hesitate to add to the numerous existing systems by inventing one of their own, will doubtless welcome the second edition of the classification used in the Vanderbilt University Medical Library.¹ It was originally intended for the documentation of a large collection of reprints, a purpose which the international system might have served equally well. As revised for use on the general medical library, however, this classification certainly has merits, though in many ways O. O. Barnard's scheme² seems preferable. An important and new feature is the comprehensive index with over 2000 entries, but the value of this has been considerably reduced by the maze-like collation of the indexed pages.

Births, Marriages, and Deaths

BIRTHS

FLEW.—On June 10th, at Heath street, Hampstead N.W., the wife of Dr J. D. S. Flew of a daughter.
GAYUS.—On June 10th at a nursing home in London to Dr Irene Kenworthy Gayus—a son and daughter.
SOPER.—On June 7th, at High Wycombe Bucks the wife of Flight Lieut R. L. Soper R.A.F. Medical Service of a daughter.
SPICER.—On June 3rd at Kampala, Uganda the wife of Dr J. R. Spicer of a son.

MARRIAGES

GAWNE-SVOBODOVA.—On June 12th, at St Mary's Cadezang-gardens Douglas W. O. Gawne M.B. to Anna Maria Svoבודה daughter of Ladislav Svoבודה, of Popovic, Czechoslovakia.
MORTON-WOODHEAD.—On June 8th, at St Ethelburga's Bishopsgate Harold James Storrs Morton M.D. to Nancy Sybilla Vincent Woodhead of Aldbury Herts.
NEWTON-DAVIES-WHITTAKER.—On June 9th at the Priory Church of St Bartholomew the Great London, Lieut-Col O. Newton Davis M.C. I.M.S. to Mrs Kathleen Mary Whittaker, widow of Squadron Leader J. T. Whittaker, M.C. R.A.F. of Belfast.
WILLIAMS-CROCKER.—On June 10th at Parkstone Hugh Morgan Williams F.R.C.S. to Jean Esmé Crocker, of Parkstone.

DEATHS

COGAN.—On June 9th at Northampton Ico Fyson Cogan, J.P. M.R.C.S. Eng. L.R.C.P. Fdn., in his 89th year.
COLLINSON.—On June 9th at Preston Frederick William Collinson, M.D. F.R.C.S. Edin., in his 81st year.
DAVIDSON.—On June 12th at Guildford George Edward Davidson M.B. Camb. of Shere aged 59.
RIDLEY.—On June 8th at Leicester, Nicholas Charles Ridley R.N. (ret'd) M.B. Lond. F.R.C.S. Eng.
WALDMEIER.—On June 2nd in London Frederick John Waldmeier, L.S.A. Lond. M.R.C.S. Eng.
V.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

A STUDY OF CRETINISM IN LONDON

WITH ESPECIAL REFERENCE TO MENTAL DEVELOPMENT AND PROBLEMS OF GROWTH

By AUDREY LEWIS M.D. Adelaide M.R.C.P. Lond.

CLINICAL DIRECTOR AND LECTURER IN PSYCHIATRY MAUDSLAY HOSPITAL, DENMARK HILL, S.E.

With the assistance of

NANCY SAMUEL, B.A. Dip. Psych. Lond.

LATE PSYCHOLOGIST AT THE HOSPITAL AND

JANET GALLOWAY M.A. Edin.

LATE RESEARCH PSYCHIATRIC SOCIAL WORKER AT THE HOSPITAL

The following investigation was undertaken for the purpose of studying the psychological effects of thyroid deficiency in childhood and what benefit substitution therapy provided for the mental retardation. As the material accumulated other questions presented themselves (chiefly concerned with growth) and led to some alteration in the intended method of presentation.

METHOD OF ASCERTAINMENT

For the first problem mentioned above it was desirable to examine patients who had definite retardation; a search was therefore made in the institutions for mental deficiency. The permission of the medical superintendents* of Leavesden Darenth The Manor The Fountain Caterham and Tooting Bec Hospitals made it possible to examine all the patients diagnosed as cretins in these institutions for defectives conducted by the London County Council. As they represented a population selected for defect it was impossible to use them for an assessment of the beneficial results of treatment by the co-operation of a number of physicians attached to voluntary hospitals; a collection of cases diagnosed as cretin or juvenile myxoedema was obtained which was not open to this objection. The bulk of the cases from voluntary hospitals came from two sources—the London Hospital and St. Thomas's Hospital. The latter were outpatients—23 of them—whom Dr. H. Gardiner Hill put at our disposal for this investigation. The records of the London Hospital when searched through for the last thirty five years yielded the names of 40 in patients in whom the diagnosis of juvenile myxoedema or cretinism had been made. Besides the patients from St. Thomas's and the London and those found in the mental deficiency institutions of the L.C.C. others less systematically collected were got from various out-patient departments (King's College The Queen's, Hackney road Paddington Green and the Maudsley Hospitals)*. The Central Association for Mental Welfare was also approached; they supplied a list of patients some of whom were available for examination. It was not possible to be sure that one had by the above means obtained a good sample of all those in London who have suffered from thyroid deficiency during childhood but it seemed possible that the collection would include most varieties of course and treatment as well as of severity of illness. In all, 145 cases were collected of whom 89 were examined. The remainder were either dead (6 cases)

or unavailable for physical and psychological examination in some of those latter where the diagnosis had been beyond question details of their family history, personality &c. were obtained. Ten of the cases examined were rejected because the diagnosis was doubtful or definitely erroneous.

The ages of the cretins tested ranged from 3 to 58 eleven were 12 years old or less, twenty three were more than 12 and less than 21 years old, fourteen were in the next decade (21-30) seventeen between 31 and 40 twelve between 41 and 50 and two were over 50.

INVESTIGATION

The patients were examined physically they were inspected the texture of the skin felt and measurements chiefly of height and hand dimensions; made. In 35 cases the impedance angle was measured by Mrs. M. A. B. Brazier Ph.D. at the Maudsley Hospital. A psychological examination was made in detail by one of us (N.S.): the Binet-Simon test was applied where the degree of deficiency was very great the Merrill Palmer and the Gesell methods of assessing intellectual development were used instead. The Goddard form board the Woodworth Wells substitution test, and manikin vocabulary and reading and writing tests were also employed. The general demeanour of the subject and his attitude towards the examination were recorded and particular note taken of the speed of his performances—e.g. in tying a bow, and carrying out the Goddard form board test. Fuller inquiries were also made by one of us (J.G.) who visited the homes of the patients and obtained from the relatives a detailed history which together with the hospital records gave a fairly complete picture of the patient's personality and development. The family history was also investigated. The condition of the mother in pregnancy the type of birth weight at birth history of fits in infancy and childhood ages of sitting up walking talking teething and the attainment of clean habits and of sexual maturity were among the data collected. Details of speech as regards quality of voice mispronunciation and extent of voluntary usage of speech were also noted. Consideration of many of these details must be excluded here for want of space.

PHYSICAL FEATURES

The familiar signs of the condition were found to be present in differing degrees and combinations. Some of the cases were as typical as the illustrations in text-books others had a characteristic face skeleton and gait but their skin and hair were normal. Those who presented difficulty in diagnosis were either free from nearly all the recognised physical features of the condition or might have been cases of mongoloid deficiency. As regards the latter in only one instance was there still doubt after careful examination the balance of evidence favoured mongolism. The former physically negative cases however raised a difficult problem: were they to be included on the history alone? Inasmuch as some other cases which had been previously diagnosed as cretins were rejected after investigation—e.g. one was found to be a hydrocephalic idiot—it seemed partial to accept all these without present evidence of the condition. On the other hand to exclude them would be to eliminate any case in which treatment had been entirely effective in clearing up the symptoms. A scrutiny of the hospital records written when the patient was first seen and a detailed history from

*We would like to record our warm thanks to the many physicians who so kindly made records and patients available to us.

the parents, made it possible to include these cases—except a case of adult myxœdema. It may be reasonably concluded that all of the patients upon whom the following report is based had at some time in their childhood shown recognisable symptoms of thyroid deficiency.

The hope of correlating amount of treatment with persistence of physical signs proved vain. Except for skeletal changes, the physical features cannot be measured, and are difficult even to rank in order of severity. The amount and continuity of treatment with thyroid can rarely be measured. Such data are therefore unsuitable for statistical analysis. There were other difficulties, which are discussed below in connexion with the effect of treatment and mental development. Such crude comparisons as could be made between treatment and disappearance of physical signs are given below, as well as the data concerning stature (see Table). It was found easier to compare physical measurements with mental measurements than to compare either with amount of treatment.

MENTAL FEATURES

Text-books give meagre descriptions of the mental changes due to thyroid deficiency in early childhood. Slowness is the characteristic insisted on. Still says "Slowness of the mental processes is the most distinguishing mental feature of the cretin. In temper he is usually amiable and placid, not to say stolid. He acquires clean habits, and is not destructive." There is moreover some disagreement as to the effect of adequate treatment on mental development. Fordyce says, for example, that if careful treatment is commenced early and conscientiously continued, the children at the best may become indistinguishable, physically and mentally, from normal children—a view held also by Cockayne and by John Thomson—whereas Still, on this point, says that "when the educational attainments of even the best of them are inquired into, they are obviously below the normal. Some cases are reported to have become perfectly normal, but I think this must be very exceptional." Many authorities agree with Still—e.g., Petterson, and Kimball and Marine. All writers hold that the mental improvement is seldom as satisfactory as the physical, spasticity is regarded as an ominous sign (cf. Rolleston). Some Austrian and Swiss investigators have gone more fully into the mental characteristics of cretins. The endemic form has been the more fully studied and reported in systematic treatises, because of the large material available. De Quervain gives a lively account, tallying with those of other writers. He stresses the slowness of the cretins, their conservatism and need for security, their good memory for places, their tendency to collect and hoard, to imitate others, and to like praise. They dodge trouble, love eating, and show little emotion, except when they have rare and brief outbursts of rage or brood discontentedly. As Maffei pointed out, they are by no means incapable of learning and reasoning, or of utilising general concepts. But such observations cannot be taken as applying necessarily to the sporadic cases of cretinism under consideration in this paper. De Quervain, though he does not go as far as Zondek, draws a distinction between the two forms, and even describes mental differences between cretins who have a goitre and those who have not, he also thinks that many of the more engaging characteristics of the cretins under his care are those of the Alpine peasants in general and are independent of the cretinism, though somewhat coloured by the cretin's optimism.

In the admirably full description given by Gamper this point is stressed, the torpidity and other features of the cretins may be seen in a mild form throughout the local population. The writers emphasise, moreover, that no specific features can be found in the psychic structure and dynamics of cretins which would make recognition of the thyroid deficiency possible from the mental state alone, there is a torpor which is myxœdematous, and a defect, not accessible to thyroid therapy, which is attributable to arrest of cerebral development and changes in cerebral structure. This is also the view of Wagner Jauregg.

In the literature of sporadic cretinism, very little is to be found about the details of the mental changes. Kornfeld, and Lazar and Nobel have made investigations, but it is doubtful whether the cretinism in their cases may not have been of the endemic sort. They found a great delay in the development of motor functions, such as grasping, sitting, and crawling, to this they attributed much of the apparent mental impairment, since the child had not the usual early mastery of means of getting at grips with the environment by his movements, nor, when he did acquire it, had he the curiosity and other stimuli to use it. Lazar and Nobel say they know no case in which treatment has led to complete mental normality. Kornfeld, who carried out intelligence tests on a small number of cases, did not find parallelism between somatic and psychic effects of treatment, and he emphasised that the deficient auditory attention, poverty of ideas and associations, and few volitional acts of the cretin made special pedagogic training necessary if the best intellectual improvement was to be attained, by such training he was able to get improvement in understanding reading, and talking. It seems probable, however, that the benefit from special education here is the same as that obtained in other forms of mental defect, whether general or special, it would not be required if hormone therapy had repaired the intellectual defect as well as it does the physical. Bronstein and Brown examined 20 children, and found the intelligence quotient to be below 70 in all but 2. Kimball and Marine considered that with adequate treatment cretins might reach a mental age of eight years.

In the investigation here reported, a description of the personality was first arrived at from direct observation of the patients during examination, and from detailed discussion of their traits with their parents, siblings, or others—e.g., nurses and doctors who knew them well. Often information was obtained from more than one such source.

The following description of one of the patients is a typical account of the more striking features of the personality of these people.

"She is exceedingly stubborn. When she is not humoured, or you cross her in any way, she will sit solidly in a chair for hours sulking. She is very slow to understand, or to do what she is told, however simple it is. She has no initiative. You have to tell her to do the same thing day after day. She rarely speaks of her own accord, but will sit mum sooner than ask for anything she wants. She is very particular about being clean and likes to have all her clothes tidy and fresh. She will do whatever you want her to if you promise her a reward. She is very pig-headed and insists on having her own way in spite of all reason."

Slowness was the characteristic most often remarked upon. It is recorded as a salient feature in three quarters of the cases—"painfully slow, no idea of time, you have to prod her all the time." Nearly a third of them were placid, though this depended

somewhat on their circumstances, for example some who at home had been spiteful and bad tempered were contented when they got into the routine of an institution. It was noteworthy that only 4 of the 70 patients were reported to be of a depressive temperament; 2 were prone to attacks of excitement with transient hallucinations when overdozed with thyroid and many flared up if much provoked (when I jawed at her she would fire up' as was said by the mother of one girl, who was mostly content to sit like a block"). Obstunacy was a frequent trait. Note worthy and little remarked upon by any previous writers was the prominence of traits that are more common in obsessional patients than any others—excessive care about order and cleanliness with a proneness to repeat their behaviour. This was conspicuous in at least a quarter of the cases and was in contrast to their general indifference and slowness. Thus one apathetic cretin was described as most painstaking and thorough and slow over everything she does. She must polish the stairs although she has been told not to; she polishes an electric switch in a dark cupboard although it can't be seen. She is always washing herself and her clothes. A few others showed related attributes: they were thrifty or given to hoarding trifles.

Half of them were fairly sociable or friendly. Hypochondriacal tendencies and suspiciousness also occurred but had little or no relationship to the cretinism. Most of the patients showed the foregoing attributes more when they stopped taking their thyroid tablets. Inquiries about personality were made in another 18 patients who were not available for examination but whose medical history was that of unequivocal thyroid deficiency in childhood: of these no less than 15 were reported to be placid or apathetic, and 10 showed obsessional traits.

PSYCHOLOGICAL TESTS

The most important feature of the psychological testing was the estimation of mental age by the customary Binet method confirmed or replaced by the Merrill Palmer test in those too low in the scale to be suitable for Binet testing; in 2 cases the Gesell method of testing infants was employed. The

notorious difficulties in ranking adults by a Binet test would make it desirable to give the scores in terms of 'mental age' rather than intelligence quotient but as 10 of the subjects were less than fourteen years old they could not be included in such

FIG. 1.—Distribution of intelligence as measured by tests, in 70 cretins

a series. It was therefore necessary to grade the subjects according to intelligence quotient. Owing to the unrepresentative method of selection it would not be justifiable to compare the frequency curve of the intelligence quotients in these subjects with that which is obtained when a true sample of the average population is tested. It is however clear from Fig. 1 that, although the number of mentally defective people is high, no less than a fifth of the subjects had intelligence quotients which fell within the range of what is usually called normal—i.e. above 80. Somewhat contrary to expectation there was in the individual cases no more scattering of successes over several years than is usually found when these tests are given to an average population. Certain special tests were however done better or worse than they might be by non-cretinous subjects.

As slowness seemed so striking a feature in these subjects various tests were specially employed because speed was a factor taken into account in scoring them. Of these the chief were the Goddard or Seguin form board the Woodworth Wells substitution test and the numerous Merrill Palmer tests in which time of performance determines the score—e.g. manikin matching cube-pyramid pink tower picture puzzles. By scoring these in terms of mental age it was possible to compare the speed of performance with the general level of intelligence (Fig. 2). In spite of the incompleteness of such a method it gives valuable information confirming the clinical impression and showing that the slowness may be notable in those whose intelligence quotient is not far below normal or is actually normal; consequently such people may in school and elsewhere give an impression of greater deficiency in intelligence than is actually the case (cf. Ziehen). It is also evident that slowness in the performance of intellectual tasks may be greater than that exhibited in ordinary motility. This is in conformity with Kossowitz's observation that there may be remarkable improvement in motility after treatment but it partly invalidates his view that the improvement in motility supplies a measure of the general psychological improvement.

FIG. 2.—Relation of speed to intelligence in a group of cretins.

Speed ratio = $\frac{\text{mental age in speed tests}}{\text{mental age in intelligence tests}} \times 100$

The apparent lessening or even reversal of the disparity in some of the cases with low intelligence quotient is partly attributable to the preponderance, among intelligence tests at this level, of tests in which speed is an important factor, and to the figures employed in scoring and computing the ratio.

Vocabulary tests were also given to the subjects, and a similar procedure—i.e., comparison between mental age so estimated and mental age measured by the customary Binet tests—indicated that there was a slight superiority in respect of vocabulary over what is customarily found in non cretinous persons. This is in keeping with the observations of de Quervain. Few of those with an intelligence quotient below 80 could articulate clearly; they slurred their consonants and in many instances used *F* for *Th*, and other childish mispronunciations. This was more common in those with severe defect, who also had, for the most part, husky, gruff voices, and little to say.

The results of the intelligence tests on this sample, which is not necessarily representative, do not in themselves indicate more than that some people who have thyroid deficiency in childhood can become intellectually quite normal, and that in this disease every gradation can occur from normality to idiocy. For fuller use of the findings, it is necessary to compare them with the age of onset of the illness, its severity, the adequacy of treatment (as to dosage, continuity, and promptness of administration after the onset of symptoms), and the other, i.e., physical, evidences of the disorder now evident. On many of these points certainty is unobtainable. Still less can the innate endowment of the affected individuals be assessed, it is not unlikely, for example, that a few of these people might have been of poor intelligence even if they had not had any thyroid deficiency. This last problem can best be met by considering the general level of intelligence in their family, especially among their siblings. The other points as to the illness and its adequate treatment have been settled, as far as was possible, by considering the details of their illness obtainable from hospital records and their parents' recollection, and then grading the cases as to adequacy of treatment on a five point scale (see Table).

FAMILY HISTORY

1 *Familial intelligence*—In 14 families there were one or, rarely, more members (parents or siblings) who were described as dull or feeble minded, apart from cretinism. Of these, only six persons were certified defectives or imbeciles. In 4 families one parent was feeble minded or dull, and in two cases a collateral was recorded as defective. These data are of course, not complete, and are given mainly to indicate that the general level of intelligence may be assumed to have been average in the majority of the patients, had they not had thyroid deficiency.

2 *Thyroid disorder*—Of the "familial" incidence of thyroid disease it is not possible to say more than that apart from 4 families in which there were two or more cretins, in five cases a sibling also had "cretinoid" features, and in one case a sibling was hyperthyroid, in another a sister had a goitre, two had myxædema. In seven there were sub-thyroid features in the mother, in four they were present on the father's side. In one the mother had a goitre until the birth of the child, and in another the mother was hyperthyroid and her mother had had myxædema. Many of the families were of short stature so that there seems a possibility that a cretinoid constitution may predispose to the illness, the data do not warrant a conclusion.

3 *Familial cretinism*—One of the 3 families in which several cretin members were examined is of interest (see L H, F H, and A H, in Table†). In this family there were four cretins, the most severely affected having died when 43 years of age. Eleven other children had died in infancy of causes unknown, and three were normal. The mother, an active woman, was slight in build though not short, but her features were cretinoid (her nose was flat, the eyes far apart, and the skin somewhat flabby). None of the other maternal collaterals nor members of the father's family were cretinoid or short. In another family with a brother and sister mildly affected neither the parents nor any collaterals showed cretinoid features or short stature. The female patient had been born during the war, when the mother was very anxious, and there was a history of fits in the mother's family. In the third family (where two brothers were cretins) the mother had a goitre, which disappeared at the birth of the elder cretin. There were seven other healthy children surviving to adult age, all successful in their work, and of good physique. One is a police man. The father was also in the Metropolitan Police, and came of very healthy stock. One of the cretins' healthy siblings has, however, a strong facial resemblance to the elder cretin.

4 *Mental disorder*—In 11 families there was a history of mental disorder (the diagnosis of which cannot now be determined), in 3, one or more siblings had fits, in 2, the siblings were deaf or deaf and dumb.

5 *External factors*—An external factor could seldom be discovered or held responsible for the disease. There had been a difficult or prolonged labour in 20 cases. One patient was syphilitic, another had had meningitis. It is noteworthy that 12 were reported as having had one or more fits, but only 2 of these were reported as having been born asphyxiated or after a difficult labour.

In an additional 18 cases investigated as to familial incidence of abnormality, there were 4 instances of fraternal imbecility, 2 of fraternal goitre, 1 of paternal cretinism. Late menarche in the mother was found occasionally here as in the larger group.

AGE OF ONSET

The age of onset can be determined satisfactorily only by medical records made at the time. Unfortunately, since most of these cases had been seen as out-patients, their records are no longer available, most hospitals destroying their out-patient notes after fifteen years. For those who were in patients, or whose parents have photographs and other data less deceptive than their memory, some estimate can be made. It seems that definite signs of thyroid deficiency had been noticed by the doctor or parent before the end of the first year in twenty patients, of whom the intelligence quotients were found to be still low, varying between 70 and idiocy which defied measurement. In ten more, signs had been noticed before the end of their second year. The latest recorded ages of onset among the remainder were 8, 9, and 12, the corresponding intelligence quotients being respectively 69, 80, and 102. It looks as though, other things being equal, the earlier the onset the worse the outlook, but the data are, as already pointed out, unsatisfactory, and closer inspection of the details of the early history as recalled by the parents suggests that signs of thyroid deficiency could probably have been noted very much earlier than they had been in the majority.

† The Table appears in the concluding part of the paper to be published next week.

of the cases. This is also indicated by a large number of instances in which walking and talking were acquired later than the third year (in just two thirds of the cases). Clean habits were remembered as having been attained before the end of the third year

FIG. 3.—Relation of intelligence to standing height in a group of cretins.

in only a third of the cases. In 31 others there was delay in the rest it was not recorded.

INTERVAL BEFORE TREATMENT

In ascertaining the interval before treatment began there are much the same difficulties as in regard to the preceding question. In 26 cases treatment had been instituted promptly—i.e. less than a year after symptoms were first noticed. At the cost of anticipating some other points as to adequacy of treatment, it is worth recording here that in one case where treatment had commenced when the patient was only four months old and had been continued with scarcely any interruption since the intelligence quotient is now only 34 and that in another whose symptoms appeared at the age of eighteen months and were immediately treated, the intelligence quotient is only 27 though thyroid administration had gone on steadily ever since moreover as a paradoxical instance of the opposite kind a man who showed some symptoms soon after birth had no treatment until he was thirty-one, and yet has an intelligence quotient of 63. There are cases in the series where symptoms had been noticed before the age of three no treatment had been instituted for ten years or more but the intelligence quotient is within normal range the most striking instance being a girl with an intelligence quotient of 101 and typical cretin appearance whose symptoms began during the first six months of life yet she had no treatment until she was eleven and then it was stopped for good after a year. It would be a manifest error to conclude from these cases that treatment is as effective when tardy as when prompt it is however legitimate to suppose that in some cases conspicuous physical evidence of cretinism may not be associated with gross mental deficiency irrespective of whether treatment has been given at all or been started late. The relationship of physical to mental retardation of development is discussed below as is also the adequacy of treatment.

RELATIONSHIP OF MENTAL TO PHYSICAL DEVELOPMENT

Fig. 3 shows the relation of height to intelligence quotient. The individual figures are given in the Table.

There was no reason to suppose that the physical and the mental development would in these cases have run parallel or that standing height is the best criterion

of defects of physical development. If it be assumed that thyroid deficiency leads to an arrest of development, the comparable data would be those of children. The correlation here is sometimes made between intelligence quotient and actual height sometimes between intelligence quotient and the comparable relative measure—i.e. the deviation from the average height for each age-sex group. There is a slight positive correlation varying between 0.14 ± 0.03 (Murdoch and Sullivan) 0.45 ± 0.026 for boys, 0.3 ± 0.028 for girls (Dawson) and 0.22 ± 0.036 for gifted boys 0.21 ± 0.38 for gifted girls (Terman). There is in short a definite but slight correlation between height and intelligence in children.

It is however unsafe to assume that the effect of thyroid deficiency is to arrest development as a whole it may only retard development and its effect may be selective on different organs and functions. On these matters there is a large body of evidence.

MENSTRUAL FISTULÆ *

WITH A NOTE ON THE SIGNIFICANCE OF TRANSUTERINE MENSTRUATION

By R. GLYN MALIPHANT, M.D. M.R.C.P. Lond.
F.R.C.S. Eng. M.C.O.G.

GYNECOLOGIST, CARDIFF ROYAL INFIRMARY LECTURER
IN OBSTETRICS AND GYNECOLOGY, WELSH NATIONAL
SCHOOL OF MEDICINE

In 1928 Max Ballin suggested the term 'menstrual fistula' for a sinus in a laparotomy scar characterised by the periodic discharge of blood more or less coincident with menstruation. It may be assumed that such a sinus communicates either with the uterine mucosa or with aberrant endometrial tissue but it is only to the former that the term 'fistula' is strictly applicable. Endometriomata have a symptomatology and pathology of their own and in this paper I propose to confine the title 'menstrual fistula' to cases in which connexion with the uterine cavity is established.

Fistulous tracts leading from the uterus to the abdominal wall are almost always sequelæ of an operation and their symptoms are pathognomonic. After operation the wound fails to heal completely and a small sinus remains which discharges dark blood at the time of the menses. In some cases the skin unites and the menstrual discharge collects as a subcutaneous hæmatoma to rupture externally later.

CASE REPORT

Mrs. A., aged 30 with one child of 5 years was admitted to the Cardiff Royal Infirmary in March 1930 with a discharging wound in the left groin. The wound ordinarily drained pus but at the menstrual periods blood issued from it freely. Menstruation was regular unaccompanied by pain and of ten days duration. During the last few years there had been a slightly increased menstrual loss but no intermenstrual bleeding had occurred either from the wound or vaginally. The woman had previously been admitted to the surgical side of the hospital on two occasions and the surgical note-books furnished the following history—

In March 1931 she was admitted as an emergency with pain in the right iliac fossa. Appendicitis was

Read before the Midland Obstetrical and Gynaecological Society May 25th 1937

The apparent lessening or even reversal of the disparity in some of the cases with low intelligence quotient is partly attributable to the preponderance, among intelligence tests at this level, of tests in which speed is an important factor, and to the figures employed in scoring and computing the ratio.

MENSTRUAL FISTULÆ*

WITH A NOTE ON THE SIGNIFICANCE OF TRANSUTERINE MENSTRUATION

By R GLYN MALIPHANT M.D. M.R.C.P. Lond.
F.R.C.S. Eng. M.C.O.

GYNECOLOGIST, CARDIFF ROYAL INFIRMARY; LECTURER
IN OBSTETRICS AND GYNECOLOGY, WELSH NATIONAL
SCHOOL OF MEDICINE

In 1928 Max Ballin suggested the term 'menstrual fistula' for a sinus in a laparotomy scar characterised by the periodic discharge of blood more or less coincident with menstruation. It may be assumed that such a sinus communicates either with the uterine mucosa or with aberrant endometrial tissue but it is only to the former that the term 'fistula' is strictly applicable. Endometriomata have a symptomatology and pathology of their own and in this paper I propose to confine the title 'menstrual fistula' to cases in which connexion with the uterine cavity is established.

Fistulous tracts leading from the uterus to the abdominal wall are almost always sequelæ of an operation and their symptoms are pathognomonic. After operation the wound fails to heal completely and a small sinus remains which discharges dark blood at the time of the menses. In some cases the skin unites and the menstrual discharge collects as a subcutaneous hematoma to rupture externally later.

CASE REPORT

Mrs. A., aged 39 with one child of 5 years was admitted to the Cardiff Royal Infirmary in March 1936 with a discharging wound in the left groin. The wound ordinarily drained pus but at the menstrual periods blood issued from it freely. Menstruation was regular unaccompanied by pain and of ten days duration. During the last few years there had been a slightly increased menstrual loss but no intermenstrual bleeding had occurred either from the wound or vaginally. The woman had previously been admitted to the surgical side of the hospital on two occasions and the surgical note-books furnished the following history:—

In March 1931 she was admitted as an emergency with pain in the right iliac fossa. Appendicitis was

Read before the Midland Obstetrical and Gynaecological Society May 28th 1937

suspected and the abdomen was opened through a right paramedian incision. The vermiform appendix was only superficially congested, but the right appendages were acutely inflamed, and thin yellow pus was found in the pelvis. Right salpingectomy and appendicectomy were performed. No comment was made on the state of the adnexæ on the left side.

She remained well until October, 1932, when she was readmitted with a tense painful fluctuating swelling in the left groin, immediately above the inner two thirds of Poupart's ligament. An incision 3 in. long was made over the swelling in the line of the inguinal canal. The tissues were dissected down to the external oblique muscle which was divided along its fibres. This opened an abscess full of foul-smelling pus, which communicated with an intraperitoneal abscess by an opening too small to admit one finger. Two drainage tubes were inserted into the abscess cavity and the wound was closed in layers. The pus was sterile on culture and the drainage tubes were removed next day. The inguinal wound did not heal and a sinus remained which had since regularly discharged blood coincidentally with menstruation. The blood appeared almost simultaneously with the onset of the menstrual flow, and disappeared a few hours after the menses ceased.

When she was transferred to the gynaecological department in March, 1936, her general condition was fairly good. There were two scars in the anterior abdominal wall, a well healed paramedian scar, and one in the left groin running a short distance above and parallel with Poupart's ligament. In the centre of the latter there was a small opening from which dark blood was exuding. The uterus was normal in size, but somewhat fixed, and no gross lesion could be detected in the appendages. The tissues about the sinus were indurated but no definite tumour was palpable. The sinus admitted a probe for a distance of an inch, and on injecting methyl violet into it the fluid escaped from the cervix.

In view of the chronicity of the condition and the annoyance caused by the constant discharge, it was decided to operate. After closing the mouth of the fistula, an elliptical incision was made around it and the scar of the previous operation was excised. On opening the peritoneal cavity, the pelvic organs were found buried in adhesions. The free end of the left fallopian tube was fixed to the posterior aspect of the inguinal wound and the canal in the parietes was continuous with the tubal lumen. The uterus and ovaries were macroscopically normal. The left fallopian tube and the canal in the abdominal wall were removed in one piece, and the abdomen was closed. The post operative course was uneventful. Menstruation occurred a few weeks after the operation and the wound remained dry. When last seen the patient was in good health, and the wound in the groin was soundly healed.

The tract in the abdominal wall and the attached fallopian tube measured 5 in. The tubal wall was thickened and on microscopic examination showed tuberculous endosalpingitis with numerous giant-cell systems. The canal in the parietes was lined throughout with granulation tissue, and the examination of many sections failed to show any tuberculous disease or glandular tissue in its wall.

DISCUSSION ON ÆTIOLOGY

Clinical reports of uteroparietal fistulæ are not common, particularly in this country, but there are 70 cases referred to in the literature. These fall in two groups which are anatomically and ætiologically distinct.

In the first group the communication between the uterine cavity and abdominal wall is direct. Fistulæ of this type may follow ventrofixation

(Bircher 1910) or myomectomy (Ballin 1928), but in most of the cases reported they have been incidental to a previous Cæsarean section. In 1922 Loieq found accounts of 28 cases of uterine fistulæ following Cæsarean section, and added one of his own. Similar ones have since been recorded by Puccioni (1925), Price (1928), Brayne (1930), and Devraigne, Banzet, and Mayer (1930), bringing the total to 37. Faulty operative technique, infection, and subsequent adhesion of the uterine and parietal wounds are the principal causes of fistula formation after Cæsarean section, but the use of non absorbable suture material in the uterus is probably a contributory factor. Uteroparietal union is of major importance, and it may be for this reason that fistula of the uterus is a sequel which seems to be peculiar to the upper-segment operation.

In the second group the connexion between the uterus and abdominal wall is indirect via one of the fallopian tubes or tubal stumps. Indirect uteroparietal fistulæ are rare at the present time, but half a century ago they were common complications of gynaecological operations. In the early days of ovariectomy, when it was customary to fix the ovarian pedicle in the abdominal wound, the tubal stump often became the site of a menstrual fistula, but these fistulæ, unlike the type seen nowadays, usually closed without delay. Spencer Wells (1882) refers to this sequel of ovariectomy in the following words:

"Then after the wound is closed, it is said to lead to a re-opening each month, and an escape of some menstrual fluid. And this is true in some—perhaps in nearly a third of the cases. But if the patient be prepared for it, it is not of the slightest consequence. The fallopian tube almost always contracts completely after a few months and there is no further escape. I can recollect only two cases where it has continued up to the date of the last report from the patient, and then it caused but slight inconvenience. If menstrual fluid can escape through the partially closed fallopian tube fixed in the cicatrized wound, so it may escape if the tube be left within the peritoneal cavity, and the result may be a fatal hæmatocele."

Fixation of the fallopian tube or tubal stump to the parietes is probably essential to the development of a tubo abdominal fistula, and under modern surgical conditions such fixation is almost always the result of infection. Thus pelvic sepsis imitates closely the effect of the deliberate extraperitoneal fixation of the tubal stump of the last century.

There are three instances on record of indirect uterine fistulæ of spontaneous origin. One followed the rupture of a pelvic abscess in the region of the umbilicus (Deverre 1920), another appeared in the scar of a laparotomy performed 16 years previously (Tortora and Sanvitale 1930), and in the third case, an advanced extra uterine gestation became attached to and fistulous in the anterior abdominal wall. After discharging fetal parts, the fistula continued to discharge blood at intervals, in addition to a small amount of fecal matter (Bouzel 1884).

Occasionally the condition has followed salpingo oophorectomy performed by the usual ligature method in a potentially clean field (Ballin 1928, Draps 1929), but some element of infection seems to have been operative in each instance. In Draps's case there was an additional mechanical factor—namely, complete stenosis of the cervix following amputation—and the fistula was the sole outlet for the menstrual discharge.

These cases are however exceptional, and the great majority of tubo-abdominal fistulæ follow operations performed for gross pelvic infection—such as the

removal of infected appendages or the drainage of an appendiceal or tubo-ovarian abscess (Masson and Simon 1928 Buscho and Curthe 1920 Brady 1930). In salpingectomy the use of non absorbable suture material in the presence of infection and the slipping of the ligature on the tubal stump are probably important causal factors. Non-absorbable suture material was removed at the second operation in three cases of tubo abdominal fistula seen at the Mayo Clinic (Masson and Simon 1928).

The formation of an indirect menstrual fistula depends upon three conditions—adhesion of the fallopian tube or tubal stump to the abdominal wall, patency of the tubal lumen and reflux of menstrual blood from the uterus. It is generally recognised that transtubal menstruation may occur under certain circumstances. It has already been noted that Spencer Wells observed an escape of menstrual blood from the tubal stump in nearly a third of his cases of ovariectomy. Pelvic infection often leads to adhesion of the adnexa to the parietes but in such circumstances the third factor—patency of the tubal lumen—is unusual, and it is the incompatibility of these two conditions that probably accounts for the rarity of tubo-abdominal fistula. In pyococcal infection the fimbrial extremity of the fallopian tube tends to close early. In tuberculous salpingitis on the contrary the tubal lumen is more often preserved (Frank 1931) and a striking feature of this review of indirect menstrual fistula is the relatively high incidence of associated pelvic tuberculosis. In the series of 16 menstrual fistula collected by Masson and Simon (1928) from the records of the Mayo Clinic 5 were associated with adnexal tuberculosis. Iribarne (1927) Ballin (1928) Mesa (1929) and Jeanneney and Laporte (1932) have also described cases of tuberculous salpingitis with menstrual abdominal fistula, and another instance of this association is published in this paper.

There are now records of approximately 30 cases of indirect menstrual fistula and 10 of these have occurred in conjunction with peritoneal or adnexal tuberculosis.

DIAGNOSIS

Granulation tissue may bleed about the time of the menses but the blood is usually bright red and the relationship of the hemorrhage to menstruation is not constant. The diagnosis of menstrual bleeding rests on the regular occurrence of dark hemorrhage limited to the catamenia and the only condition which can in this respect simulate a menstrual fistula is a sinus in connexion with an area of ectopic endometrial tissue. Extragenital endometriomata are not uncommon, and there are numerous records of endometrial tumours developing in laparotomy scars. Endometrial grafts however rarely grow in wounds which suppurate and fail to heal by first intention so endometriomata which discharge on to the skin surface are rare. One of the first examples was recorded by Fletcher Shaw in 1925 of an Adeno-myoma of the round ligament which menstruated through an inguinal incision and in this case the tumour was incised under a mistaken diagnosis. Menstrual sinuses in association with endometriomata have since been described by Ballin (1928) Schaaffner (1929), and Martin Michon and Pigeaud (1933).

Clinically these cases closely resemble uterine fistula and as Martin suggests have probably been the cause of some confusion in the past. The endometrioma is sometimes palpable beneath the sinus and it may undergo the painful premenstrual swelling typical of such tumours. A uterine fistula, on the

contrary is usually painless and as a rule the amount of discharge from it is much greater. In these respects a menstrual fistula may differ from a menstrual sinus but the former diagnosis is only established when communication with the uterine cavity is demonstrated either radiographically by the injection of coloured fluids or at operation.

Ballin (1928) reported one case in which the two conditions were combined. When a uterine fistula contains an endometrial tumour in its wall the hemorrhagic discharge may be derived from the uterine cavity, from the wall of the fistula or from both. Such a combination of lesions is probably exceptional, but can only be ruled out after endometriosis of the abdominal wall has been excluded by microscopic examination of the entire fistulous tract. The few histological records available suggest that the canal in the abdominal wall is usually lined with ordinary granulation tissue but remains of glandular crypts have occasionally been described (Devraigne 1930 Jeanneney and Laporte 1932). In the case recorded by Jeanneney and Laporte the wall of a tubo-abdominal fistula which followed the removal of a tuberculous pyosalpinx, was lined with tuberculous granulation tissue.

PROGNOSIS AND TREATMENT

Spontaneous healing of a uterine fistula is rare and it is for the annoyance and persistence of the condition that operation is usually required. But a direct uterine fistula carries in addition the risks of uteroperitoneal fixation in relation to childbearing and in such a case it is advisable to operate not merely for the inconvenience of the discharge but to avoid the obstetrical consequences.

In an uncomplicated case the operative risk is small but interference should be postponed so long as the fistula is acutely inflamed. An indirect fistula may be excised with the corresponding fallopian tube. If the fistula leads directly to the uterus the tract with the old scar may be completely excised, and the wound in the uterus carefully closed but many of these cases require hysterectomy. Tortora and Sanvitale (1930) succeeded in causing a direct uterine fistula to heal by dilating the cervix widely, curetting the sinus and draining the uterus vaginally for several days.

If the fistula communicates with bowel as well as with the uterus prognosis for operation is grave. Menstrual focal fistula have been recorded by Bouzou (1884) Puccioni (1925) Ballin (1928) and Mesa (1929).

Although fertility is probably reduced by the coexisting infection pregnancy may occur and proceed normally. In the event of pregnancy this may be allowed to continue to term, and Caesarean section performed through the posterior uterine wall as recommended by Devraigne Banzet and Mayer (1930). If an attempt be made to excise the fistula in the course of the Caesarean operation the risks of peritonitis are considerable (Martin 1933).

RETROGRADE MENSTRUATION

Not the least interesting feature of a study of tubo abdominal fistula is its bearing on transtubal menstruation. Many authorities consider that this plays an important part in pelvic pathology. It is a link of outstanding importance in Sampson's hypothesis of ovarian endometriosis and it also provides a possible mode of dissemination for uterine cancer. In 1925 Sampson reported that blood may occasionally be seen dripping from the fimbrial ends of the fallopian tubes of women operated upon at the time of the menses and in Goodall's opinion (1934) this observation

has since been confirmed by so many surgeons that its occurrence can no longer be a matter of doubt. Nevertheless many gynaecologists of wide experience have never observed it. Novak (1926) operated upon 13 women during menstruation without seeing any blood entering the peritoneal cavity, and argues further that menstruation is normally unaccompanied by any sign or symptom of peritoneal irritation such as is found with a tubal abortion. Novak's experience corresponds to that of many surgeons, so the conclusion must be that although transtubal menstruation may occur, it does so very rarely, and even in those cases in which menstrual spill has been observed it is hard to exclude some pathological basis for the regurgitation.

Radiography has now shown that the mechanism which prevents the free passage of fluid from the uterine cavity into the fallopian tubes is the sphincteric action of the uterotubal junction. When air or fluid is injected into the uterus, the isthmus and intramural portions of the tubes contract, thereby preventing for a time any leakage through the tubal ostia, and thus spasm has occasionally led to the incorrect assumption of tubal obstruction. But the sphincter is not strong enough to offer lasting resistance to injection, and is usually overcome by a pressure of 90 or 100 mm of mercury. Heuser (1924) noted that when the uterine cornu is in contraction, the uterotubal sphincter is closed, and it is no doubt for this reason that in uterine hæmorrhage the blood does not more commonly enter the peritoneal cavity. Whether the closure of the ostia depends upon uterine or tubal action is still debated, but the copious reflux which may take place through a tubo abdominal fistula suggests that contraction of the uterus is not sufficient to prevent leakage, and that there is a true sphincteric apparatus in the fallopian tube.

It is evident that in tubo abdominal menstrual fistulae this sphincteric mechanism is defective. It has been noted that fistulae of this type have, in the past, commonly followed ovariectomy, but are nowadays almost without exception associated with pelvic inflammation. It may be presumed that both sets of circumstances in some way disturb tubal action—division of the infundibulopelvic ligament in ovariectomy destroys an important section of the tubal nerve supply, and its musculature is damaged in pelvic infection—so the retrograde menstruation may be regarded as a manifestation of abnormal permeability of the uterotubal junction.

It is well recognised that the permeability of the fallopian tubes varies considerably in different subjects. Goodall (1934) has described 4 cases in which vaginal douche fluid has gained access to the peritoneal cavity, and in these it was subsequently shown that a pressure of 40 mm of mercury was sufficient to force gas through the tubal ostia. He concludes that in such women the oviducts are unusually patulous, and points out that a developmental anomaly of this nature may be an occasional cause of menstrual spill. Predisposition to retrograde menstruation would also result from deficiency and lack of control of the uterotubal sphincter, and the associated pathology of indirect menstrual fistula suggests that this may be a sequel of tubal inflammation. The frequency with which chronic salpingitis is found as a complicating lesion of ovarian endometriosis lends some support to this view.

SUMMARY

A case of uteroparietal fistula is described, which followed the drainage of a tuberculous pelvic abscess, and other cases on record are reviewed.

Uteroparietal fistulae are of two types. In the first there is direct connexion with the uterine cavity, and the fistula is usually the sequel of Cæsarean section. The second type is seen in conjunction with pelvic inflammation, and communication with the uterine cavity is indirect via one of the fallopian tubes or tubal stumps. In approximately one-third of the recorded cases indirect uterine fistula has been associated with peritoneal or adnexal tuberculosis.

The free transtubal menstruation often conspicuous in cases of tubo abdominal fistula signifies a breakdown of the sphincteric mechanism at the uterotubal junction. Chronic inflammation, by disturbing normal tubal physiology, may play an important part in the causation of pelvic endometriosis.

DUODENITIS AND ITS SURGICAL TREATMENT

By GERSHON GARRY, M.D. Tufts, U.S.A.

SURGEON TO THE SHAARE ZEDEK HOSPITAL, JERUSALEM

BEFORE discussing the surgical treatment of duodenitis a brief review of the clinical aspect of the disease should be of interest. Till comparatively recent times duodenal ulcer was the most clearly defined disease, but recently duodenal dysfunction and duodenitis are becoming more and more realised as important factors. There have now been a series of reports on the subject of duodenitis 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 and it is generally admitted that often its diagnosis is made only with considerable difficulty.

SYMPTOMS AND SIGNS

First in importance is the differential diagnosis from duodenal ulcers. Other pathological states, however, such as gall bladder disease, pancreatitis, appendicitis and colitis closely resemble and may often accompany the disease, so that careful clinical judgment is required to arrive at a correct conclusion.

While the symptomatology of duodenitis is not characteristic and may leave us in doubt about the

actual condition the X ray examination is of considerable help in establishing the diagnosis.^{18,21} Kirklin (1934) in his valuable contribution on the subject emphasises several findings which he considers pathognomonic of duodenitis:

"First in importance among the signs is an abnormally increased irritability of the duodenum. In typical instances the hyperirritability is manifested in an intense spasticity and a hypermotility of the duodenum. The barium races through so rapidly that there is a scant opportunity to inspect the shadow. The bulb is frequently small and grossly deformed, both on its mesial and lateral borders and the configuration of the deformity varies quickly from moment to moment. Further the bulbular shadow lacks the density commonly seen in cases of frank ulcers; it is thin and indistinct and its margins are hazy. A second characteristic is the mucosa pattern which is coarsely and irregularly reticular and is depicted as translucent islets lying in a denser network. This appearance is perhaps attributable to puckering of the mucosa by spastic contractions of its muscularis. A third characteristic of simple duodenitis is the absence of an ulcer crater. Neither marginal niche nor central fleck can be seen. Finally uncomplicated duodenitis is marked almost invariably by absence of gastric retention or other evidence of obstruction whereas such obstruction occurs in more than 25 per cent of cases of true ulcer. It is clear both from the roentgenologic and pathologic studies that duodenitis does not tend to produce organic stenosis. Completing the typical syndrome of duodenitis is a small hypertonic stomach with active sometimes disordered peristalsis. Like roentgenologic signs the foregoing marks of duodenitis vary in emphasis, and only a minority of cases are so typical that the diagnosis is obvious. Thus among the last thirty-two cases only eight were diagnosed as duodenitis; four were deemed negative and a diagnosis of duodenal ulcer was made in twenty.

In a series of our own comprising 20 cases of simple duodenitis verified by operation and in part by the microscopic examination of excised tissues the diagnosis was not made in any of the cases previous to operation either clinically or roentgenologically. In 13 the diagnosis was duodenal ulcer and in the remainder gall bladder disease, appendicitis and colitis. The examination of the gastric contents was not characteristic. The fasting contents showed an average total acidity of 30 units and free acid 14 after Ewald's test meal the figures were 50 and 30 respectively. The stool examinations for occult blood were positive in 60 per cent. The X ray

findings were positive for duodenal ulcer in 15 of the series. 3 were diagnosed as gall bladder disease and 2 as appendico-colitis. The operative findings

FIG. 1 (Case 1).—Section of duodenum showing muscularis with displaced pancreatic tissue composed of solid alveoli and dilated excretory ducts ($\times 50$).

helped in establishing the diagnosis and comprised changes in the duodenal wall such as congestion of the serous coat, thickening of the entire duodenal wall, and adhesions to the neighbouring organs in some of the cases. No signs of an ulcer were detected in any of our series. In 5 cases where gastroduodenal resection was performed we were able to examine the interior of the duodenum both grossly and microscopically. It presented signs of general inflammation without ulceration.

In discussing the surgical treatment it should be emphasized that duodenitis is essentially a medical condition and surgery is resorted to only in the most obstinate cases where medical means are of no avail. The surgical procedures at our disposal comprise gastro-enterostomy which affords a certain rest to the diseased area, duodeno-jejunosomy serving a like purpose, and gastroduodenal resection a more radical procedure affording a complete and permanent rest to the diseased duodenum.

The experiences with gastro-enterostomy have not been very favourable. In the majority of cases the operation failed to procure the desired results. We performed it in 13 of our series. The follow-up records showed good results in 3 cases, bad results in 6 and the rest of the cases could not be traced. Some authors claim satisfactory results with duodeno-jejunosomy and consider it the method of choice. In recent years however gastroduodenal resection was performed in certain cases of duodenitis. On Konjetzny's suggestion (1934) cases with threatening haematemesis associated with erosive gastritis were treated with gastroduodenal resection (also Finsterer 1923). We extended this indication to a broader field and used gastroduodenal resection in cases when duodenitis without haematemesis was clinically severe and resisted all internal therapy. While our limited material in no way justifies general conclusions it may nevertheless act as a stimulus for further studies. A brief review of our cases is given below.

REPORT OF FIVE CASES

CASE 1

A man, aged 24, was admitted to the hospital on June 12th 1933 with the following history: "Seven

FIG. 2 (Case 2).—Above: section of pylorus. Inflammatory infiltration by eosinophils and neutrophils, especially in the muscular layer ($\times 100$). Below: Cluster of inflammatory cells ($\times 500$).

FIG 3 (Case 3)—(A) Above section of duodenum showing inflammatory infiltration of muscularis ($\times 120$) (B) Below infiltration of mucosa with plasma cells partly degenerated ($\times 600$)

years ago he began to complain of attacks of pain in the right hypochondrium, pains lasting several weeks and recurring every few months. At the onset the pains were in relation to the intake of food, but lately they were continuous, nausea but no vomiting. Bowels acted regularly. Radiograms on May 23rd, 1931, showed considerable hypersecretion and a tender and deformed duodenal bulb. The diagnosis of duodenal ulcer was made and subsequently a gastro-enterostomy was performed which relieved complaints only for a brief period. Physical examination on admission revealed tenderness in epigastrium and right hypochondrium. Gastric analysis following Ewald's test-meal showed total acidity 79 and free acid 30. The stool had no occult blood. Radiogram taken on June 15th, 1933, showed a patent anastomosis functioning well and a deformed duodenal bulb.

Operation on June 20th. The duodenum showed congestion of its serous coat and general thickening of its wall. No ulcer was detected. Gastroduodenal resection was performed and previous anastomosis left intact.

Pathological report—Duodeno-pylorus segment 5 cm. long. On opening lumen no ulcer was found and a small diverticulum is seen on the duodenal side which extends only into the mucosa. Microscopically the mucosa shows eosinophils sparingly distributed around the crypts and adjacent to the lymph follicles. The muscularis, below the above mentioned diverticulum, shows displaced pancreatic tissue composed of solid alveoli and a large number of dilated excretory ducts (Fig 1). Pericanalicular infiltrations of neutrophilic leucocytes, an occasional eosinophilic leucocyte, histiocytes, and some lymphocytes are seen near the dilated ducts. The solid gland tissue shows no inflammatory infiltration. Further away the muscularis shows few eosinophils and an occasional neutrophil, more so near the lymphatic layer. **Diagnosis** duodenum containing displaced pancreatic tissue with dilated excretory ducts, duodenitis.

Subsequent course—Convalescence uneventful, since operation he has been free from symptoms.

CASE 2

A man, aged 34, was admitted to the hospital on August 27th, 1933, with a history of epigastric pain of one year's duration. The attacks occurred an hour or two after meals and lasted for several hours. During the period of his illness he had a number of attacks which lasted two to three weeks at a stretch and left him in an exhausted state. Dieting gave no relief. Alkaline as well as other internal therapy was of no avail. Physical examination showed tenderness in the epigastrium and

right hypochondrium. Gastric analysis following Ewald's test-meal showed total acidity 79 and free acid 68. Stool was positive for occult blood. Urine negative. Leucocytes 5800. Radiogram showed considerable hypersecretion and hyperperistalsis, bulbous duodenum tender and with a "clover leaf" shadow. **Diagnosis** ulcer duodeni.

Operation on August 30th. The duodenum showed congestion of serous coat and general thickening of its wall. No ulcer detected. Gastroduodenal resection performed in accordance with Billroth 2.

Pathological report—Duodeno-pylorus segment 5.5 cm. long. On opening lumen mucosa found intact. Microscopically section of pylorus shows no changes in the mucosa except for the presence of a moderate number of plasma cells and an occasional eosinophil. The submucosa is oedematous and shows no inflammatory signs. The muscularis shows cell clusters composed of eosinophils and neutrophils infiltrating the tissue in all directions, chiefly near the smaller vessels. Smaller foci as well as single cells are seen also in other parts of the muscularis. The infiltration is more abundant towards the periphery in marked contrast to the inner muscular layer where it is scantier. Section of the duodenum presents a similar picture, in the mucosa the leucocytes are more abundant, the submucosa is oedematous but otherwise shows no inflammatory changes. The infiltration of the muscularis is less abundant and foci of lesser extent. **Diagnosis** gastritis and duodenitis (Fig 2).

Subsequent course—Convalescence uneventful, since operation he has been free from symptoms.

CASE 3

A man, aged 29, was admitted to the hospital on Sept 10th, 1932, with a history of attacks of epigastric pains of twelve years' duration. The attacks lasted several weeks and recurred every two to three months. The pains were relieved immediately following intake of food but returned two hours subsequently and with greater intensity, nausea but no vomiting. Bowels constipated. Physical examination showed considerable tenderness in the epigastrium. Gastric analysis following Ewald's test-meal gave a total acidity of 75 and free acid 32. Stool was positive for occult blood. Urine negative. Leucocytes 7100. Radiogram showed a deformed bulbous with elongation of lateral process. The stomach emptied itself completely four hours after the barium meal. **Diagnosis** duodenal ulcer.

Operation on Sept 15th. The duodenum showed congestion of its serosa and thickening of entire wall. No ulcer found. Gastroduodenal resection in accordance with Billroth 2.

Pathological report—Duodeno-pylorus segment 5 cm. long. On opening lumen mucosa found intact. Micro-

FIG 4 (Case 4)—Section of duodenum showing inflammatory infiltration (perivascular) of muscularis ($\times 500$)

scopically section of the duodenum shows mucosa with an abundance of lymph follicles and large germinal centres. The stroma of the mucosa is also rich in plasma cells and lymphocytes (Fig 3A). Many cells are encountered with broken up nuclei and chromatin, which is subdivided

into two or three circular segments peripherally placed; these are plasma cells with degenerated nuclei. The muscularis mucosae show an occasional eosinophil or neutrophil. The muscularis shows in its outer layers infiltrations of eosinophils and neutrophils distributed throughout its extent; part of the infiltrations are perivascular (Fig. 3a). Several leucocytes are also seen in the adjacent fatty tissue. Diagnosis: duodenitis.

Subsequent course.—Convalescence uneventful since operation free from symptoms.

CASE 4

A man, aged 42, was admitted to the hospital on Oct. 7th, 1934 with the following history. Three years previously he was operated upon for duodenal ulcer and a gastro-ostomy was performed. This relieved him for a year. Subsequently previous symptoms returned and with greater intensity characterised by epigastric attacks coming immediately after meals and lasting for hours. At the onset of the illness the attacks recurred every two to three weeks but recently they come on daily; nausea but no vomiting. Bowels act once in three days. Abdominal distension often accompanies the constipation. Physical examination showed tenderness in the epigastric region. The stools were negative for occult blood. Urine negative. Leucocytes 9800. Radiogram showed a patent anastomosis functioning well. Duodenum tender and does not fill well. The stomach emptied completely 20 mins. after administration of barium meal.

Operation on Oct. 16th. Anastomosis found faultless. Duodenum showed thickening of entire wall. No ulcer detected. Gastroduodenal resection performed and anastomosis left intact.

Pathological report.—Gastroduodenal segment 3.5 cm. long. On opening lumen mucosa found intact. Microscopically section of the duodenum shows mucosa rich in lymph follicles. In the stroma around the crypts many plasma cells and occasionally an eosinophilic leucocyte are encountered. The muscularis shows small perivascular infiltrations composed of neutrophils and eosinophils. Leucocytes mostly eosinophils are also seen intravascularly. Section of pylorus shows plasma cells in the mucosa. The submucosa is oedematous and contains large dilated veins. The muscularis mucosae is oedematous and many lymphocytes are found. Diagnosis: gastroduodenitis (Fig. 4).

Subsequent course.—Convalescence uneventful; since operation free from symptoms.

CASE 5

A youth aged 17 was admitted to the hospital on August 6th 1931 with a history of epigastric attacks of three years duration. At the outset the attacks occurred daily and lasted half an hour. Recently the pains became continuous. There was no relationship between the pains and the intake of food. Had nausea but never vomited. Bowels were constipated. Physical examination showed tenderness in the epigastrium and right hypochondrium. Gastric analysis following Ewald's test meal showed a total acidity of 75 and free acid 32. The stool was positive for occult blood. Urine negative. Leucocytes 9000. Radiogram showed much hypersecretion and hyperperistalsis and thickened folds of gastric mucosa. The duodenal bulb emptied rapidly and was very deformed. Three hours following barium meal the stomach was two-thirds full of residue. Diagnosis: duodenal ulcer.

Operation on August 12th. The duodenum showed congestion of serosa and thickening of entire wall. No ulcer detected. Fibrous adhesions found between the duodenum and gall-bladder; the latter showed no pathological changes. Gastroduodenal resection (Billroth 2).

Pathological report.—Gastroduodenal segment 4 cm. long. On opening lumen mucosa found intact. Microscopically section of duodenum shows many plasma cells in the mucosa. The submucosa is oedematous but shows otherwise no inflammatory changes. The muscularis shows small infiltrations of neutrophils and eosinophils especially near small vessels. Diagnosis: duodenitis.

Subsequent course.—Convalescence uneventful; since operation free from symptoms.

DISCUSSION

In reviewing the microscopic findings in our cases of duodenitis we are impressed by the close resemblance between this clinical entity and that of appendicitis. In both conditions the mucosa is only lightly affected while the intensity of the process is confined largely to the muscular coats. In appendicitis the portal of entrance is through a minute break in the mucosa (the Primär-afekt of Aschoff). Except for Case 3 of our series where there was considerable infiltration of the mucosa with plasma cells partly degenerated, the mucosa had minimal pathological changes. Yet it is plausible to assume that in duodenitis the entrance of the infection is also through the mucosa and the inflammation extends from within outwards. The intensity of the inflammation varies from a moderate degree as shown by Cases 1, 4 and 5 to the very intense almost phlegmonous inflammation of the duodenal muscularis as shown by Cases 2 and 3. It is readily conceivable why the clinical manifestations of duodenitis are most intense as the inflammatory infiltration of the duodenum interferes with the physiological peristalsis of the duodenum. In Case 1 we are likewise to assume that the pericardial inflammation and not the displaced pancreatic tissue accounted for the clinical manifestations as one at times encounters displaced pancreatic tissue in other parts of the intestines without giving rise to symptoms.

Clinically these cases emphasise the problem of the diagnosis and treatment of duodenitis. As a rule there is great disproportion between the symptoms and the anatomical changes. The severest clinical manifestations often stand out in contrast to the insignificant operative findings. Under the circumstances the surgeon finds himself in a predicament about the correct diagnosis and proper procedure to be followed. As is often the case a mere exploratory operation is performed without benefiting the patient. It is therefore incumbent upon us to establish as far as possible the diagnosis before resorting to surgery. This should be based upon a painstaking X ray examination of the gastro-intestinal tract and by eliminating affections of the adjacent organs. Once the diagnosis of duodenitis is established the only recourse left for obstinate cases refusing all internal therapy is operation. Considering the unfavourable results with previous surgical procedures it appears that gastro-duodenal resection should be the method of choice.

I wish to thank Prof. S. Getzowa of the Pathological Institute Hadassah Jerusalem for the microscopical slides for the pathological reports and for her helpful advice and Dr. A. Druckman for the radiographic examinations.

GLUTEAL ANEURYSM

BY H I DEITCH, MS Lond, FRCS Eng

LATE RESIDENT SURGICAL OFFICER AT THE ROYAL INFIRMARY, BRADFORD AND

JOHN MCGHIE ROGAN, MB Edin

LATE HOUSE PHYSICIAN AT THE INFIRMARY

Gluteal aneurysm is rare, but its importance is more than academic since its prompt recognition may save a patient's life, either by securing correct treatment or by preventing a disastrous incision. Russell Howard has said that all swellings of the buttock should be regarded as gluteal aneurysms until a satisfactory contrary diagnosis has been made, and the following case report shows the wisdom of his statement.

CASE REPORT

A man aged 49, by occupation a motor mate, had been treated for 15 years for various gastric disorders and had undergone several operations 10 years previously, since when he had suffered intermittently from melena. On his admission to hospital in July, 1935, a diagnosis was made of 'achlorhydric microcytic anemia following gastro-enterostomy'. In February, 1936, he was readmitted under the care of Dr W Messer. He said he had enjoyed good health until two months previously when he began to have severe and rapidly progressive pain in the left buttock, which forced him to take to bed within a few days. Three weeks before admission he noticed a swelling in that buttock and it appeared to be increasing. On admission he was pale and emaciated. His blood count showed a hæmoglobin of 61 per cent, with a colour index of 0.63, and the typical picture of a secondary anemia. The spleen was enlarged. The greater part of the left buttock was involved in a swelling which was fluctuant and the left thigh was wasted. Clinically, his condition was graver than his blood picture suggests. Melena was absent, and no abnormality could be discovered on radiography of the alimentary tract. Some new bone formation was, however, apparent in the region of the left ilium. Dr H Franklyn reported upon it thus: "Myositis ossificans or new bone formation due to inflammatory process".

Aspiration was attempted, but failed. As the most likely diagnosis appeared to be neoplasm, the then house physician performed a biopsy, noting at the time that the specimen appeared to be blood-clot. Dr C J Young issued a pathological report to the effect that the specimen consisted of degenerated muscle fibres replaced by fibrous tissue, with no evidence of neoplasm. Soon after J M R became house physician the biopsy wound began to ooze, and the patient's condition deteriorated, and when seen by H I D he was looking desperately ill. The diagnosis of gluteal aneurysm was tentatively made, but operative treatment was considered out of the question because the patient was so ill, and the wound was therefore packed.

Three days later there was a severe secondary hæmorrhage which could not be stopped by pressure and it

became essential to explore the wound. This was done under local anesthesia while an intravenous gum-saline infusion was given pending the arrival of a blood donor. On enlarging the wound it became apparent that the gluteal swelling was a mass of tightly packed laminated blood clot and round the mass blood oozed rapidly up into the wound. A laparotomy was impossible (the pulse was almost imperceptible) so an attempt was made to pack the vessel against the great sciatic notch by turning down a flap of all the tissues at the back of the ilium, but the patient died while this was being done.

At autopsy an aneurysm of the left superior gluteal artery which had ruptured, just outside the pelvis was demonstrated, from the condition of the clot and the remnants of the vessel it seemed probable that the rupture had occurred some weeks previously. The clot had separated the muscles from the dorsum of the ilium and measured about two pints.

COMMENT

The cause of gluteal aneurysm varies. The majority are traumatic in origin, but a few are spontaneous. The case described above must be included among the latter since no history of trauma could be elicited. Of about 80 cases recorded (Matas, Rupp) 49 were traumatic and 23 spontaneous, the cause of the remainder being undetermined. Of those due to trauma half followed stab wounds and half falls on, or blows on, the buttocks. Rupp states that the condition is commoner on the left side, but may be bilateral.

Signs and symptoms.—Pain in the buttock is usually the first symptom, but there may also be pressure symptoms from involvement of the nerves. Then as a rule comes a gluteal swelling, small if the aneurysm is intact, large if it has ruptured. (Although, as in a case reported by Haggard, an unruptured aneurysm may be "enormous") Till the blood has clotted the swelling will give an expansile impulse with perhaps a thrill and a bruit.

Diagnosis.—A careful history and examination will be of great value and further information may be obtained by aspiration of the swelling and by radiography. It may be difficult to distinguish a ruptured aneurysm from an abscess, from osteosarcoma (which may be pulsatile), and from rarer conditions such as lymphosarcoma.

Prognosis.—Matas says that gluteal aneurysms "tend to rupture spontaneously and sometimes choke up the thigh with massive extravasations of blood which cause death from hæmorrhage very rapidly".

Treatment consists in ligating the internal iliac artery and obliterating the sac to prevent recurrence (Haggard, Frost, Adams, Maguire). Where the aneurysm is small, a proximal and distal ligation with extirpation of the sac may be satisfactory. Adams describes in detail the treatment of an aneurysm developing after a gunshot wound thus:—

First operation. Ligation of the internal iliac artery with subsequent disappearance of the swelling which, however, recurred in a week's time. **Second operation.** Ligation of the gluteal and obturator arteries in the pelvis. This was ineffective. **Third operation.** the sac was incised and the vessels entering the sac ligated (Antyllus's operation). This was successful.

We wish to thank Dr F W Eurich and Dr Messer for allowing us to publish this case.

mice used was 12, so that the average number of days survived was $100/12=8.3$

The above protocol can, therefore, be reduced to the figures shown in Table II which are available for comparison with other experiments provided the lethal dose of the infecting organism remains constant in size and virulence

Table III summarises multiple experiments using various compounds. The figures in the last column provide a reasonable assessment of comparative efficiency

In addition to the compounds shown in Table III some 28 other synthetic sulphonamide derivatives have been tested. Of these, two show considerable promise

(1) 4,4'-diaminobenzenesulphonamide tartrate (oral) had an average day survival figure of 7.5 with a dose of 10 mg in experiments involving 48 mice

(2) 4,3'-diaminobenzenesulphonamide (oral) had an average day survival figure of 7.1 with a dose of 20 mg in experiments involving 54 mice

Conclusions—Experimentally the following oral compounds are effective in the treatment of streptococcal infections in mice: *p*-aminobenzenesulphonamide, *p*-benzylaminobenzenesulphonamide, 4,4'-diaminobenzenesulphonamide tartrate and 4,3'-diaminobenzenesulphonamide. Of the soluble compounds, Prontosil (soluble) and disodium *p*-(γ -phenyl-propyl-amino) benzenesulphonamide α - γ disulphonate are less efficient than either of the above oral preparations, but are themselves equally effective

HUMAN STREPTOCOCCAL INFECTIONS

Prontosil (soluble) has been shown to be effective in puerperal infections (Colebrook and Kenny 1936 a, b), in erysipelas (Becker 1937), and in a number of other lesions which are reported singly or reviewed in annotations in *The Lancet* or *British Medical Journal* of 1936 and the current year. Foulis and Barr (1937) report favourably on *p*-aminobenzenesulphonamide in puerperal infections

TABLE IV

Disease	Cases	Success	Failure	Toxic complications
Streptococcal septicæmia	5	4	1	Nil
Erysipelas	2	2	0	"
Tonsillitis	0	7	2	"
Cellulitis	1	1	0	"

p-benzylaminobenzenesulphonamide has been less widely reported on but was found to be effective in erysipelas by Bloch Michel, Conte, and Duvel (1936) and by Peters and Havard (1937), the latter also report success in other types of streptococcal infection. My own experience with a limited number of cases proved the effectiveness of the substance in erysipelas, streptococcal septicæmia, streptococcal tonsillitis, and streptococcal cellulitis. This experience is set out in Table IV. All the patients received 2 tablets (0.5 gramme) of *p*-benzylaminobenzenesulphonamide three times a day.

EXPERIMENTAL INFECTIONS IN MICE WITH MENINGOCOCCUS

Experiments were carried out using a technique similar to that described by Proom (1937). To Dr R. A. O'Brien I am indebted both for the culture used by Proom and for a supply of mucin. The assessment

of experimental infections is very difficult owing to the relatively low virulence of the organism for mice. Huge doses of culture have to be used and mucin must be added to make the inoculation effective, a method for exalting mouse virulence has not yet been satisfactorily devised.

Table V is a typical protocol

TABLE V

No. of organisms	No. of mice	Received.	Deaths on given day—							Survived 1 week	Average survival day (7)
			1	2	3	4	5	6	7		
10 ⁸	6	Nil	1	5	0	0	0	0	0	0	0.8
10 ⁷	6	"	1	3	0	0	0	0	0	3	2.8
10 ⁶	6	"	0	2	0	0	0	1	0	3	4.6
10 ⁵	6	<i>p</i> -aminobenzenesulphonamide 25 mg (three doses only)	1	0	0	0	0	0	0	6	5.8
10 ⁴	6		1	0	0	0	0	1	0	4	3.5
10 ³	6		0	0	0	0	0	0	0	0	7.0

As the result of a series of experiments for the testing of various compounds the following average day survivals were obtained over an observation period of 7 days, using 10⁸ dose of culture. Control 10⁸ (42 mice) 0.75 days, *p*-aminobenzenesulphonamide, 25 mg (24 mice) 4.1 days, *p*-benzylaminobenzenesulphonamide, 50 mg (18 mice) 0.6 days, disodium *p*-(γ -phenyl-propyl-amino) benzenesulphonamide α - γ -disulphonate, 30 mg (12 mice) 0.8 days, 4,4'-diaminobenzenesulphonamide tartrate, 10 mg (12 mice) 4.2 days, 4,3'-diaminobenzenesulphonamide, 20 mg (12 mice) 1.2 days.

Conclusion—*p*-aminobenzenesulphonamide is effective against meningococcus as previously found by Proom (1937), this is borne out by preliminary clinical reports (Schwentker, Gelman, and Long 1937). 4,4'-diaminobenzenesulphonamide tartrate is equally effective.

TABLE VI

Showing Toxicity of Various Compounds and Comparative Efficiency in Experimental Infections in 20-gramme Mice

Compound	Infection	Dose (mg)	Efficiency figure (with maximum possible in parentheses)	Toxicity to 20 g. mice
Prontosil (soluble) (subcutaneous)	Streptococ	7.5	0.8 (10)	80 mg (subcut.) is tolerated (Medien and Chemie 1936)
<i>p</i> -aminobenzenesulphonamide	Streptococ	25	7.7 (10)	Markedly toxic at 50 mg. Fatal at 150 mg.
	Meningococ	25	4.1 (7)	
	Pneumococ	25	1.2 (7)	
<i>p</i> -benzylaminobenzenesulphonamide	Streptococ	50	7.9 (10)	Non toxic at 200 mg (Halpern and Mayer 1937)
	Meningococ	50	0.6 (7)	
	Pneumococ	50	0.5 (7)	
Disodium <i>p</i> -(γ -phenyl-propyl-amino) benzenesulphonamide α - γ disulphonate	Streptococ	10	6.6 (10)	Slightly toxic at 200 mg (Halpern and Mayer 1937)
	Meningococ	10	0.8 (7)	
	Pneumococ	30	0.9 (7)	
4,4'-diaminobenzenesulphonamide tartrate	Streptococ	10	7.5 (10)	Non toxic in doses of 60 mg
	Meningococ	10	1.2 (7)	
	Pneumococ	10	3 (7)	
4,3'-diaminobenzenesulphonamide	Streptococ	20	7.1 (10)	Non toxic in doses of 100-150 mg
	Meningococ	20	1.2 (7)	
	Pneumococ	20	4 (7)	

Streptococ meningococ, pneumococ = streptococcus meningococcus pneumococcus

PNEUMOCOCCUS

A small number of experiments have been performed with pneumococcus Type I. No evidence has been found that either *p*-aminobenzenesulphonamide or *p*-benzylaminobenzenesulphonamide or the disodium sulphonamide sulphionate compound has any action in preventing death in experimental infections. On the other hand both 4,4-diaminobenzenesulphonanilide tartrate and 4,3-diaminobenzenesulphonanilide have a definite protective action. An indication of this is given in Table VI.

TOXICITY IN THE HUMAN SUBJECT

Prontosil (soluble) and *p*-aminobenzenesulphonamide have an irritant action on the urinary tract in a large proportion of cases (Colebrook and Kenny 1936a Foulis and Barr 1937) sulphæmoglobinæmia is also common (Colebrook and Kenny 1936a Foulis and Barr 1937 Paton and Eaton 1937). In the human subject no cases of nervous-system complications such as occur in mice have been reported but one such has come to my knowledge.

No cases of sulphæmoglobinæmia occurred during the treatment of 215 cases of streptococcal infection with *p*-benzylaminobenzenesulphonamide by Peters and Havard (1937) nor have any been observed in my own experience of some 20 cases. Nausea and vomiting are seen occasionally with all three preparations.

DISCUSSION

The aim of any therapeutic procedure is to combine efficiency with safety. The efficiency of the various compounds available for the treatment of streptococcal infections is summarised in Table VI where the known toxic doses for mice are also stated. The most common complications with *p*-aminobenzenesulphonamide are sulphæmoglobinæmia and methæmoglobinæmia and though there appears to have been very little mortality from these complications they cannot be regarded as a desirable burden for even a convalescent patient to bear. *p*-benzylaminobenzenesulphonamide would appear less likely to produce these complications both from experimental evidence and from clinical report; the substance is equally active and is therefore worthy of clinical trial.

As to the soluble compounds there is again a bigger margin of safety with disodium *p*-(γ -phenyl)propyl amino) benzenesulphonamide α - γ -disulphonate than with prontosil (soluble) as judged from animal experiment. And in my own experience I have given 20 c.cm. of the first named compound daily for five days by the intravenous route without the slightest toxic symptom; experimentally there is nothing to choose between the efficiency of the two compounds.

It should be noted that *p*-benzylaminobenzenesulphonamide and the soluble disodium sulphonamide sulphionate compound are both inactive in meningococcal infections whilst *p*-aminobenzenesulphonamide is active. All three compounds are quite inactive in pneumococcal infections.

SUMMARY

(1) The oral preparations *p*-benzylaminobenzenesulphonamide and *p*-aminobenzenesulphonamide are equally effective in experimental streptococcal infections. The former is very much less toxic than the latter.

(2) Of preparations for injection prontosil (soluble) and disodium *p*-(γ -phenyl)propyl-amino) benzenesulphonamide α - γ -disulphonate are equally effective in experimental streptococcal infections; the latter is less toxic than the former.

(3) *p*-aminobenzenesulphonamide is effective in experimental meningococcal infections. *p*-benzylaminobenzenesulphonamide and disodium *p*-(γ -phenyl)propyl amino) benzenesulphonamide α - γ -disulphonate are inactive.

(4) Two diaminobenzenesulphonanilide compounds have been found to have a considerable polyarticular action; they are well tolerated and one protects against streptococcus pneumococcus and meningococcus the other against streptococcus and pneumococcus.

I am greatly indebted to Messrs. May and Baker Limited for supplies of *p*-benzylaminobenzenesulphonamide (Proseptazine) of disodium *p*-(γ -phenyl)propyl amino) benzenesulphonamide α - γ -disulphonate (Soluseptazine) and of the other experimental products referred to in this paper.

DEATH FROM AGRANULOCYTOSIS AFTER TREATMENT WITH PRONTOSIL FLAVUM

By J G G BORST M.D.

SENIOR ASSISTANT IN THE INTERNAL HOSPITAL DEPARTMENT OF MEDICINE, UNIVERSITY OF AMSTERDAM

ALTHOUGH the benzenesulphonamide compounds were introduced only a few years ago they are already widely used. Originally they were given only in streptococcal infections but lately they have also been recommended for meningococcal infections¹ and pyelocystitis.² It soon became clear however that they were liable to have serious toxic effects and cases of sulphæmoglobinæmia,³ methæmoglobinæmia⁴ and nitritoid crisis⁵ have been reported.

Between September and December 1936 I treated 13 cases of *B. coli* pyelocystitis with Prontosil Flavum and 5 of these developed toxic symptoms. One patient became dyspnoeic and developed Cheyne Stokes respiration; she was seriously ill for one day but not cyanotic. As in September I had not yet read Colebrook's article⁶ I did not test the blood for sulphæmoglobin and methæmoglobin; the number of leucocytes and the differential leucocyte count were normal. Three patients complained of paresthesia in the face and of the hands; two of them at the same time had sensory disturbances; while doing their hair they could not actually feel it. None of these patients received more than six tablets of 300 mg. prontosil flavum daily and after discontinuing administration of the drug the symptoms disappeared in a few days.

The fifth patient developed agranulocytosis.

She was a woman of 61 and was taken into the wards on Nov. 21st 1936 for pyelocystitis. In 1922 and 1926 she had been treated in the gynaecological ward for haemorrhagic discharge and gum bleeding while blue

patches were showing on her arms also. The treatment then given included curettage, irradiation of the spleen with X rays, injection of horse serum of the patient's own blood, and of gelatin. A diagnosis of thrombopenic purpura was made (A complete history of the case is unfortunately not available.) In 1929 she was examined in the out patient department of Prof Rutting because she had a few ptechie on her legs. A blood count showed red cells, 4,420,000 per c mm, hæmoglobin, 83 per cent, platelets, slightly increased (estimated roughly), white cells, 10,500 per c mm (eosinophils 2 per cent, basophils 1½ per cent, stab cells 7 per cent, polymorphonuclears 45½ per cent, lymphocytes 37 per cent, monocytes 7 per cent). No important symptoms of disease developed

Temperature and pulse chart showing dosage of prontosil flavum administered (1.8 g and 2.4 g daily)

after 1929, and the patient suffered from nothing except frequency of micturition

A fortnight before admission pains in the loins and strangury developed, the urine becoming cloudy and foul. On admission on Nov 21st her temperature was 39°C (102°F). Nothing abnormal was found in lungs, heart, or abdomen. The urine contained ½ per mille albumin, and was full of pus and coli bacilli. A blood count on Nov 23rd showed 8000 white cells per c mm (eosinophils 2 per cent, metamyelocytes (juveniles) 1 per cent, stab cells 12 per cent, polymorphonuclears 51 per cent, lymphocytes 11 per cent, plasma cells 7 per cent, and monocytes 10 per cent. The Wassermann and Sachs Georgi test were negative, the sedimentation rate of the blood was 83 mm in the first hour. From Nov 21st till Dec 3rd the patient received daily six tablets of 300 mg prontosil flavum. At first the temperature dropped, but after a few days it rose again to 39°C (see Chart), though the urine contained neither leucocytes nor bacteria, and a culture remained sterile. The patient had no complaint. The prontosil treatment was discontinued, the temperature dropped, but leucocytes and coli bacilli reappeared in the urine, and after a few days the temperature went up again.

On Dec 11th prontosil treatment was resumed, but half an hour after taking the first two tablets the patient had cold shivers, the temperature rising to 40°C (104°F). The blood showed the full picture of infection with 14,000 white cells (polymorphonuclears 62 per cent, stab cells 28 per cent, metamyelocytes (juveniles) 2 per cent, lymphocytes 1 per cent, and monocytes 13 per cent). The number of platelets, roughly estimated, was normal. Hæmoglobin 78 per cent. The patient complained of pain in the left side, and there was much tenderness on pressure in the region of the left kidney.

From Dec 11th to 21st the patient again received six tablets of prontosil flavum daily, and again the leucocytes and bacteria disappeared from the urine within a few days, while the temperature dropped. But this time also the temperature did not become quite normal as it varied between 37.2 and 37.8°C. As I suspected that, although the urine was sterile, the infection of the kidney itself had not yet been cured, I increased the dose of prontosil to eight tablets daily on Dec 22nd.

On Dec 28th the patient complained of general discomfort the temperature in the evening being 38.1°C (100.5°F). No special attention was paid to this because there was an outbreak of influenza among the other patients, four of nine women in the ward having temperatures above 38°C. On Dec 29th the patient showed tympanic

percussion of the left lower lobe accompanied by bronchial breath sounds, the temperature rising to 39°C (102.2°F). Prontosil treatment was discontinued. A blood count on Dec 30th showed hæmoglobin 70 per cent, red cells, 3,330,000 (slight anisocytosis), reticulocytes 0.8 per cent, platelets (of normal appearance under the microscope), 270,000 per c mm, white cells, 1225 (eosinophils 0, basophils 2½ per cent, polymorphonuclears, 25 per cent, lymphocytes 83½ per cent, monocytes 11½ per cent). That same evening the patient had difficulty in swallowing the throat being slightly red. On the morning of Dec 31st the number of leucocytes had dropped to 900 per c mm, the differential count being polymorphonuclears 1 per cent, lymphocytes 87 per cent, monocytes 12 per cent. In

the afternoon the patient died. Post mortem atelectasis of the left lower lobe was found, no signs of pneumonia were apparent either naked-eye or on microscopical examination. Also the angina was not demonstrable any more, it certainly had not been severe during life. There were no more signs of inflammation of the bladder and left and right pelvis, sections of the kidneys showed a few small round-cell infiltrations in the medulla, otherwise kidneys were normal. No abnormalities to account for the high temperature and death were found. As the autopsy took place 28 hours after death, the films taken from the bone

marrow were (as was expected) unsuitable for drawing any conclusions.

During her stay in the wards this patient had no remedies except prontosil flavum, some dilute hydrochloric acid to facilitate its absorption, and (on Dec 10th) 15 grammes of castor oil. There can I think be no doubt about the close connexion between the use of prontosil flavum and the occurrence of agranulocytosis in this case, but the patient's unusual previous history may indicate some predisposing disease of the bone marrow.

It is not clear why so many of the 13 patients in this series showed toxic symptoms during prontosil treatment. With 2 exceptions, none of the patients were seriously ill before they were treated, during the whole course of their illness I had had no fever. Prontosil flavum is generally given to patients suffering from streptococcal sepsis, and where the illness is already severe slight symptoms of intoxication are not easily recognised, so that even a serious complication like agranulocytosis may not alter the clinical picture radically enough to attract attention. In the case recorded here the first diagnosis was one of influenzal pneumonia.

As a result of our unfavourable experience prontosil flavum treatment was stopped, but in 11 more cases *p* aminobenzenesulphonamide (Prontosil Album) was given. This drug also caused toxic effects, but these were fairly harmless. In all patients feeling ill or having fever, the blood was repeatedly examined, but no qualitative or quantitative abnormalities of the leucocytes were found.

CLINICAL AND LABORATORY NOTES

A CASE OF PARATYPHOID A

By HENRY COHEN M.D. Liverp. F.R.C.P. Lond.
PROFESSOR OF MEDICINE, UNIVERSITY OF LIVERPOOL;
HONORARY PHYSICIAN, ROYAL INFIRMARY,
LIVERPOOL

A. G. C. FOLLIOTT M.B. Dubl.

AND

HEDLEY D. WRIGHT M.D. D.Sc. M.R.C.P. Edin.
PROFESSOR OF BACTERIOLOGY, UNIVERSITY OF
LIVERPOOL

BEFORE the Great War paratyphoid fever due to *Bact. paratyphosum* A was almost unknown in England. Lohmann (1910) could find no cases recorded from Great Britain up to 1912 and although Windsor (1916) in a study of the bacteriology of the bile, isolated the organism in two cases neither of these patients gave a history of enteric infection. During the war the incidence of the disease increased but, as Bruce White (1929) has pointed out the organism for some unknown reason failed to establish itself in western Europe after the war although epidemics due to *Bact. paratyphosum* B have not been infrequent.

We have been able to find records of only two cases in England since 1918. One is reported by Dive (1922) in a patient recently returned from Mesopotamia, and the other by Giry and Gardiner (1934) which appears to have been of local origin (Bristol). Both these cases were diagnosed serologically and the reactions in the second were somewhat anomalous. The literature however probably does not represent the actual frequency at all accu-

CASE RECORD

Our patient was a healthy man aged 26 with no relevant previous illnesses. He first experienced slight malaise on Oct. 1st 1936 but remained at work until the afternoon of the 2nd when he had to return home early because of abdominal discomfort which gradually intensified and was later associated with vomiting. He was first seen by A. G. C. on the morning of Oct. 3rd with generalised abdominal tenderness and a temperature of 100 F. There were no local signs, and next day although the abdominal pain had subsided his temperature was 101 F. and he complained of constipation. On Oct. 5th his temperature rose to 102 F. and he had severe headache though his general condition was unchanged.

The accompanying Chart records the course of the temperature from the evening of Oct. 6th onwards. On the 7th an enteric infection was suspected but agglutinations were negative and fecal culture showed no typhoid or paratyphoid bacilli. A blood culture on Oct. 8th was sterile. On the 10th two rose spots appeared on the abdomen, but the spleen was not palpable. On the 12th agglutinations were again carried out with negative results. Next day he was seen by H. C. still complaining of headache, generalised abdominal discomfort, profound weakness and constipation. He had the characteristic appearance of an enteric patient with a few rose spots on the abdomen, but the spleen was still not palpable. There was a slight bronchitis but no other chest trouble. The clinical diagnosis of an enteric infection was made and further blood tests advised. On Oct. 16th—i.e. fifteen days after the first clinical evidence of infection—a positive agglutination reaction to *Bact. paratyphosum* A was found in a dilution of 1 in 100. On the 17th he had a severe intestinal haemorrhage with profound collapse, aggravation of his abdominal pain, and his pulse rate rose to 120. Next day he passed a large quantity of blood per rectum and his previous apathy gave place to irritability. On Oct. 18th the agglutination to *Bact. paratyphosum* A rose to 1 in 320 and on the 22nd the organism was recovered from the faeces though the urine remained sterile. Gradually his clinical condition improved and his temperature remained normal after Nov. 3rd. On Nov. 27th his urine and faeces were both free of organisms of the enteric group.

Throughout the illness the spleen was not palpable; the patient had no natural movement of the bowel except on the day following the haemorrhage, there was never abdominal distension despite the fact that feeding was chiefly per rectum as the patient refused to take food by the mouth.

DISCUSSION

In attempting to find a possible source of infection, we ascertained that the patient had travelled to Hamburg on August 22nd returning on the 29th. If it be assumed that the infection occurred outside this country the incubation period would be at least thirty-three days. The man who shared the cabin with our patient was tested for agglutinins and his urine and faeces were cultured with

negative results. Although the incubation period seems lengthy if the infection occurred outside this country it is within known limits. Vincent and Muratet (1917) described a case of laboratory infection in typhoid fever where symptoms appeared first on the fortieth day.

It should be noted that the serum was in all cases

cc3

Temperature and pulse chart

ately Dr W. M. Scott (of the Pathological Laboratory Ministry of Health London) informs us that the number of official notifications of *Bact. paratyphosum* A for England since the war is three in 1921 one in 1926 one in 1927 and three in 1928. It is not certain but appears probable that all these diagnoses were based on agglutination tests.

tested against *Bact typhosum* (H and O), *Bact paratyphosum* B (H type, H group and O), and *Brucella abortus* as well as *Bact paratyphosum* A. In all cases reactions with these organisms, other than with *Bact paratyphosum* A, were completely negative (i.e., no reaction occurred in a dilution of serum of 1 in 20). The relatively late appearance of a positive Widal reaction in cases of *Bact paratyphosum* A has been noted by MacAdam (1918). In one mild case he noted its first appearance on the twenty first day, in one severe case after the fourth week, and in another in the fifth week.

The media used for the isolation of the organism from the faeces were brilliant-green eosin agar plates and sodium tetrathionate broth (Jones 1936). The interesting point was that the culture was obtained by directly plating the faeces on the brilliant green eosin agar but no growth was obtained when the faeces were inoculated into tetrathionate broth and this was plated on the solid medium after 24 hours' incubation. This enrichment method has proved very satisfactory with *Bact typhosum* and *Bact paratyphosum* B. A few experiments indicate that it is not suitable for *Bact paratyphosum* A, but it requires to be tested on more strains. Krumwiede (1917) found *Bact paratyphosum* A in the faeces most frequently in the first week.

SUMMARY

A case of paratyphoid A is recorded in which the infection occurred probably outside this country. The agglutination reaction was negative on the twelfth day but positive on the sixteenth. The organism was recovered from the faeces on the twenty second day.

AN UNUSUAL CASE OF GALL STONES

By JOHN MACKAY, M D Glasg., D P M

ASSISTANT MEDICAL OFFICER, COUNTY MENTAL HOSPITAL
 WHITTINGHAM PRESTON

A MAN, aged 44, was admitted to the County Mental Hospital, Whittingham Preston, on April 3rd, 1901. He had delusions of persecution, he was noisy and excited at times, and he suffered from auditory hallucinations. During 36 years' stay in hospital he remained deluded and was often querulous and irritable. He was convinced that there was a conspiracy against him and that electricity was being passed through him. He maintained fair health, however, until the early part of 1933, when he showed signs of cardiac insufficiency, and he slowly deteriorated physically up to the time of his death at 80 years of age on March 13th, 1937.

Post-mortem examination revealed advanced arteriosclerosis and myocardial degeneration. The mitral and tricuspid valves were thickened. But the most striking finding was a greatly enlarged gall bladder,

4½ in in length (see Figure). It contained three large stones and numerous small ones. The measurements of the three large stones were 1.25 x 1 in, 1.2 x 0.6 in, 1.75 x 2 in. The wall of the gall bladder was tightly stretched over the stones, and there was no bile present.

This case is unusual for several reasons. Firstly, although the patient was of the querulous type, he never once made complaint of abdominal pain. Secondly, routine physical examination conducted by

The gall bladder containing its stones

several medical officers failed to determine any abdominal tenderness. Thirdly, his delusional locus was the head and not the abdomen, as he imagined that electrical influences were destroying the hair of his head and were making him deaf.

I have to thank Dr A R Grant, medical superintendent, and Mr J Gates, chief laboratory assistant, for their help and interest in this case.

DUODENAL DIVERTICULA

Writing in the *Riforma Medica* (1937, 53, 590) M Donati describes a case of diverticulum of the third part of the duodenum.

The patient was a married woman aged 43. At the age of 20 she began to suffer from attacks of diarrhoea, lasting a few days and recurring at intervals of about a month. These went on for about five years, after which she was much troubled by constipation. For a year she suffered from a sense of weight in the epigastrium, increased by lying down and relieved by standing, and accompanied by distaste for food. As medical treatment failed to cure her, an X ray examination was made, and revealed a large diverticulum in connexion with the inferior limb of the duodenum. Soon afterwards the patient had an attack of acute epigastric pain and nausea, lasting 12 hours. This attack was repeated a month later and after a second (confirmatory) X ray examination, operation was decided upon. The diverticulum, which consisted only of mucosa and submucosa, was dissected out after incising the peritoneum over it, and removed. The resulting aperture in the duodenum was sutured transversely so as to avoid narrowing the lumen. Convalescence was uneventful and the symptoms were completely relieved.

Discussing the origin of these diverticula and the indications for operation, Donati emphasises the importance of a confirmatory radiography since the appearances may be deceptive and may lead to the performance of an unnecessary laparotomy. The operative procedure to be adopted can only be decided after the abdomen has been opened, the ideal is removal of the diverticulum and suture of the bowel but it may not be possible to carry this out, and in complicated or very difficult cases the surgeon may have to fall back upon a palliative operation such as gastrojejunostomy.

MEDICAL SOCIETIES

ASSOCIATION OF CLINICAL
PATHOLOGISTS

THE summer meeting of this association was held on June 12th in the pathological department of the Royal East Sussex Hospital, Hastings. Dr P. LAZARUS-BARLOW, pathologist to the hospital, occupied the chair and the meeting was devoted to various aspects of the problems of

Blood Transfusion

Dr H. F. BREWER, medical officer to the London Blood Transfusion Service, spoke on the organisation and medical administration of a voluntary blood transfusion service. He commended the aim of the British Red Cross Society to co-ordinate all such services in a national scheme. The routine running of a transfusion service was best carried out by a body independent of the hospitals making use of the donors and its medical administration was preferably centralised in the hands of a clinical pathologist. Dr Brewer advised a full re-examination of donors after ten (and multiples of ten) donations. He considered the safe minimum time interval between bleedings to be three months for men and four months for women, but there was no need to limit the number of donations given. The needle method of extraction of blood was alone permissible. Certain desiderata were emphasised—the withdrawal of blood from a donor only in the supine position, the avoidance of direct arm to arm technique, the use of a local anaesthetic at the site of needle puncture, the exclusion of iodine in the dressing and the elimination of overbleeding. He paid a tribute to Mr P. L. Oliver, the founder and honorary secretary of the London service.

The PRESIDENT (Dr S. C. Dyke) described the blood transfusion service organised for the Royal Hospital, Wolverhampton (his paper appears on p. 1538).

STORED BLOOD

Dr NORA SCHUSTER (London) described some of the experimental work on the keeping properties of blood. She said that the red cells in ordinary citrated blood remained intact for about 21 days after which hæmolytic begins. They could be preserved longer by adding glucose to the blood, and in certain physiological fluids they had been kept intact for 180 days. Red cells would remain physiologically active in the circulation of a recipient animal after having been kept for 14 days. Red cells could be kept for four weeks and retain their power of absorbing oxygen. She described the Russian method of storing blood taken from a cadaver a few hours after sudden death, which had the advantage that more could be collected from the donor and that there was no need for the addition of citrate on account of fibrinolysis. She also described methods used in France, Spain and South America for storage of blood from living donors. The medical service of the Government forces in Spain in the course of the present rebellion were using blood stored in ampoules under a positive pressure of two atmospheres for emergency use on the field. The blood was usually of Group A or O. It was administered straight into the vein from the ampoule, usually by medically unqualified orderlies or nurses. The usual period of keeping was three to four weeks. Dr Schuster showed photographs of the service supplied through the courtesy of Mr Oliver of the London

Blood Transfusion Service. Experience showed that there was no likelihood of damage from infection or the development of toxins in blood stored for one month. She discussed the possible toxic effects of hæmolytic and referred to experimental work by Bayliss from which he concluded that hæmolytic as such, was not harmful. Dr Schuster suggested that it might often be more convenient to collect blood and store it for emergencies rather than arrange for donors at short notice.

Dr R. V. Facer (Bournemouth) stated that he had on a number of occasions given blood which had been stored in the ice-chest for various periods. Nothing untoward had ever happened after six days storage. On one occasion after two weeks storage the recipient had shown jaundice and hæmoglobinuria, but there had been no serious constitutional symptoms.

Dr A. F. S. SLADDEN (Swansea) asked whether the fact that the blood in the Spanish Government Service was stored under increased atmospheric pressure might not be the explanation of its keeping qualities.

Dr J. OLIVER (London) said he was in the habit of storing blood in the ice-chest for periods up to two weeks. During the period of storage oxygen was slowly bubbled through the blood. Such blood for transfusion purposes appeared to have all the qualities of fresh blood.

Dr BREWER reported that he had twice seen severe allergic reactions after the use of stored blood. He thought that more work was required before the practice could become a matter of routine.

REACTIONS AFTER TRANSFUSION

Dr J. A. BOYCOTT (London) described three cases of anomalous blood grouping reactions. (1) A blood of Group AB appeared to be of Group A, the B agglutinating being very weak, was only demonstrated later. (2) A patient apparently of Group O was transfused with blood from a donor of that group but developed the symptoms of intravascular agglutination and died. Post mortem examination showed the usual blockage of the urinary tubules with disorganised blood pigment. The recipient's serum was subsequently found to agglutinate with the donor's red cells in vitro. Both the red cells of donor and recipient were checked and were found to be inagglutinable by the grouping serum used. It was possible that the recipient was actually of Group A or AB, and that his serum contained anti O agglutinins. (3) The serum of a patient apparently of Group AB was found to agglutinate the red cells of a known AB subject. Later it was found to agglutinate his own red cells. On putting up the red cells of this subject against known anti A and B serum at incubator temperature no agglutination occurred. Actually he belonged to Group O and the phenomenon was that of cold agglutination in this instance occurring up to a temperature of 25°C. All these cases illustrated the danger of placing too much reliance on grouping alone and the necessity of careful matching of bloods for transfusion purposes.

Dr R. J. V. PULSTHART (London) in describing certain abnormal reactions first referred to some of the effects of infusion of simple saline. In a number of cases coming to autopsy after saline infusions he had found œdema of the lungs and of other viscera, particularly the heart. He suggested that physio-

logical solutions such as that of Hartmann were preferable to normal saline. Certain reactions after transfusion of blood were in his opinion allergic, he described one case in which a transfusion was followed by severe urticaria. Four cases of transfusion with incompatible blood were described, in no case was the amount infused over 300 c cm, and all the patients recovered. Incompatible blood had been administered owing to wrong grouping, this being due to loss of potency of the grouping serum through addition of phenol as a preservative. Dr Pulvertaft stated that he had injected doses of 5-20 c cm of incompatible blood at weekly intervals into patients over long periods, no untoward symptoms had developed, and he considered sensitisation to blood previously given from the same donor an unlikely cause of reactions. He described four cases of hæmoglobinuria after transfusion in hæmolytic anæmia. The infused red cells being normal ought theoretically not to be susceptible of lysis, perhaps in these diseases the organism attained a certain red cell level and on infusion it was the subject's own red cells, and not those of the donor, that were destroyed. After splenectomy lysis after infusion of blood did not occur.

Dr N. HAMILTON FAIRLEY (London) pointed out that American figures showed that infusion into an adult of up to 350 c cm of incompatible blood had never caused death while infusion of 540 c cm or over had always done so. This suggested a critical level for the disposal of the products of hæmolysis.

Dr SCHUSTER asked why transfusions of blood are given. Two indications covered all possibilities. They might be given to replace blood in hæmorrhage or in certain of the "idiopathic" anæmias with a view to stimulating in some unknown and unspecified way the blood-forming organs. One of the commonest reasons for which blood was given was "shock." In shock without severe blood loss, transfusion of blood was not required. Far too many transfusions were being performed—Many members expressed their concurrence with this view.

Dr JANET VAUGHAN (London) was of the opinion that transfusions were given far too casually, many of the untoward incidents following transfusions were due to chilling of the infused blood, this was liable to give rise to *in-vivo* cold hæmolysis.

The PRESIDENT believed that reactions after transfusion, apart from those dependent on incompatibility, were due to inattention to essential details. The most important of these were temperature of the blood, the use (in making up solutions) of freshly glass-distilled water only, and strict cleanliness of all apparatus. The simpler the apparatus the more easily it could be kept clean. On that account he used a small glass reservoir from which the blood was run in by gravity. The rubber tubing employed was kept in short lengths which were taken apart for cleaning and united by metal joints for use. The maintenance of all apparatus and solutions in readiness for immediate use demanded the supervision of one person. Since the appointment of a single responsible blood transfusion officer reactions after transfusion had become rare at the Royal Hospital, Wolverhampton.

TECHNIQUE OF TRANSFUSION

Dr H. L. MARRIOTT and Dr A. KEWICK (London) described the uses of the transfusion of blood in large quantities by the continuous drip method. The purpose of the method was to bring the red cells of the blood up to a suitable level as quickly as possible. When large quantities of blood were infused slowly

the red cells remained in the circulation but the fluid elements were excreted. The principal indication for continuous transfusion was persistent bleeding.

Dr LAZARUS BARLOW said that in his opinion the direct method of blood transfusion was the method of choice. The blood transfused was less interfered with in this method than in any other. It did not entail the exposing of the veins of either patient or donor. In nearly 400 transfusions, the great majority of which were carried out by the direct method, no donor's vein had been exposed. A Louis Joubé syringe of 5 c cm capacity was used, No. 17 gauge. Record needles being connected to the syringe by two pieces of thin pressure tubing each about six inches long. The essential point was to keep the piston constantly on the move, once the transfusion had started, in order to prevent clotting. It might be argued that this entailed giving the blood too fast, but no ill effects from this cause had been observed. Dr Lazarus Barlow said that apart from the impossibility of getting two beds alongside one another, the only contra indications were when a constant drip transfusion was required and when a comparatively large transfusion was needed in the case of a patient whose veins were too small to admit a No. 17 gauge needle.

Dr R. OFFICER (London) described a method for post-operative blood and saline transfusion. Patients recovering from long and severe operations required large amounts of water and salt, evidences of salt deficiencies could be got from the urine which in such cases was free from or low in chlorides. Both blood and saline were administered by the "drip" method, and were kept in separate containers, Dr Officer had devised a special apparatus by which a change-over from blood to saline could be effected without undue admixture of the saline and citrated blood. This was important as the addition to citrated blood of saline often led to clotting. As a routine 500 to 700 c cm of blood was given immediately on the return of the patient from the theatre, this was followed by saline at the rate of 3½-4 pints in each twenty-four hours for forty-eight hours. In a series of 27 cases of combined excision of the rectum in which this technique had been employed there had been only 1 death.

APLASTIC ANÆMIA

Dr F. A. KNOTT (London), represented in absence by Dr Cuthbert Dukes, reported on 4 cases of aplastic anæmia treated by repeated transfusions. Dr Knott pointed out that the blood picture could by this means be restored to normal, but there was no means at present of judging whether or not the hæmopoietic system would be capable of maintaining it there. By a careful study of his cases Dr Knott arrived at the conclusion that a continued reticulocytosis was a bad prognostic sign indicating a state of strain on the part of the hæmopoietic system. In three of the four cases such a reticulocytosis had persisted and all had ended fatally. In the fourth case after repeated transfusions the reticulocytosis had disappeared and the patient was now doing well.

INTRAVASCULAR HÆMOLYSIS

Dr FAIRLEY gave a report of his observations on formation of pseudo methemoglobin in intravenous hæmolysis. He pointed out that disintegration within reticulo-endothelial cells was the normal physiological fate of the erythrocyte. Lysis in the blood stream was a pathological event. The clinical syndrome was characterised by sudden rigor, fever,

join pain anæmia hæmolytic jaundice oliguria and perhaps anuria. The pathological lesions consisted of hæmorrhoidosis, blockage of the renal tubules, toxic changes in their lining epithelium and perhaps degeneration of hepatic cells. As to the mechanism involved—extracorporeal hæmoglobin was treated as a foreign substance. Some 10 per cent. was excreted through the glomerulus and appeared in the urine if a pH of less than 6.4 was reached in the tubules, methæmoglobin and possibly acid hæmatin was formed (Dodds). In these circumstances slitting up effects followed which led to oliguria anuria nitrogen retention with high blood urea and renal acidosis characterised by a low plasma bicarbonate low serum calcium and high blood phosphorus. The remaining 90 per cent. appeared to be disposed of by the reticulo-endothelial cell system and liver the oxyhæmoglobin producing hæmatin which gave rise to hæmoglobin and hæmobilirubin. Excess of bilirubin led to pleocholia bilious stools and urobilinuria.

Recent work on blackwater fever by Farley and Bromfield had shown the presence of another pigment in the plasma allied to methæmoglobin but having its α band somewhat nearer the blue end of the spectrum (6240 Å). Unlike methæmoglobin this band was not dispersed with Stokes's reagent ammonium sulphide (10 per cent.) ammonia or hydrogen peroxide (10 vols.). The new pigment was formed both *in vivo* and *in vitro* by the action of plasma on hæmoglobin and was probably an intermediary product in the formation of hæmatin. It was not excreted by the kidneys and from this viewpoint its formation was a conservative process protective to the organism. It was constantly found in severe cases of blackwater fever and is probably ultimately formed in all instances of intravascular hæmolysis.

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY

At a meeting of this society on June 10th a paper entitled

The Psychological Approach

was read by Dr T. A. Ross. Such an approach he said had two aspects—first the understanding by the physician of his patient's illness and secondly the understanding by the patient of the origins and causes of his illness in so far as these are psychogenic. As regards the doctor's understanding of the patient's illness two views may be contrasted. According to one view there is no psychological approach—no suffering can be accepted as genuine unless there are physical signs and those who complain of such suffering should be handed over to the policeman or the priest—if only these functionaries would do their duty. According to the second view—as expressed for example by Croddick—psychogeny embraces the whole of medicine and is the key to the understanding of every patient. Whether an illness be traumatic or microbial the patient comes by his catastrophe because he wishes it, the catatrophic being preferable to something which it averts. For Croddick intention is the key to everything. But this view is unprovable—anxiety can be found in any case with a good history if we look for it industriously enough and there are many who wish for an illness who do not get it. Indeed many obviously refuse the advantage which their physical illness might confer on them and go about

courageously when they might well be and could be at rest.

Illness even if it has not originated psychogenically must soon be complicated by events. The average man does not want to be ill he wants to do a lot of things which illness will stop—to play or watch football, or play golf or go to the cinema. Illness brings fear anxiety loss of confidence in his doctor resentment against his employers hope of unearned increment and other factors inimical to recovery. Thus truth said Dr Ross lies intermediately between the doctrine of physical causation and that of pure psychogenic causation. It seems obvious that every patient presents both a mental and a physical problem. For this reason among others medical psychologists of all people have much need to look more at their patients and less at their books. Medical psychology has suffered of late from having one clinical observer of outstanding genius with no one quite competent to criticise him effectually and who is surrounded by a cohort of pretensions ready to slay any outside critic who arises.

Dr Ross related that when he began to study the effect of mind on bodily symptoms he was living and working in the Isle of Wight in isolation from others interested in the subject. There were disadvantages in this there were also considerable advantages. There are advantages in having a director supervising one's earlier cases, certainly for the early patients but the pupil tends to become subservient to the teacher to lose his critical faculties, to depend less on the picture provided by the patient and more and more on the master's ideas. When we come to the regulation that every would-be therapist must himself be analysed before he starts treating we have come to the end of originality. No one ever quite recovers from an analysis. The patient may lose his illness but every successful analysis whether of patient or of pupil, must result in the more or less permanent adoption of the analyst's views. One may hope to get a number of people well without making them subjects of transference neurosis; which may sometimes be an incurable neurosis meaning that the doctor shares the illness with the patient instead of some member of the latter's own family doing so.

All sick persons said Dr Ross demand some form of psychological approach. Even a sick horse must be so approached. There are two possible strategic methods for the psychological approach—one is analysis and the other persuasion. Whenever we take a history we probably make an interpretation—some more skillfully than others—and there is little difference between this and analysis. Whenever we give a good or a guarded or a bad prognosis we are using persuasion. Persuasion may be divided into encouragement and discouragement each has its place. There is one pitfall and one only about encouragement: it may be the last thing the patient seeks or desires in that case it may make him worse. The good doctor must believe in his treatment. No one can give encouragement unless he is a rogue about something in which he has no faith.

The analytic approach is of value in the psychoneuroses and in every kind of chronic illness who ever takes a history is fairly sure to begin to analyse. In acute illness like pneumonia or malaria there is almost no analytic approach. The analytic approach does not necessarily mean a deep analysis and a great number of psychoneurotics can be got to remain well for years without any knowledge of their infancy or young childhood. Deep analysis has its uses but every abdominal pain does not call for a laparotomy.

ROYAL SOCIETY OF MEDICINE

SECTIONS OF LARYNGOLOGY AND
OTOLOGY

THE summer meetings of these sections took place at the Norfolk and Norwich Hospital, Norwich, on June 18th and 19th.

At the section of laryngology, with Mr LIONEL COLLEDGE, the president in the chair, a discussion was held on

Orbital Cellulitis due to Sinus Infection

Mr E D D DAVIS, in opening, defined orbital cellulitis as an acute inflammation of all or part of the contents of the orbit, characterised by considerable œdema of the eyelids and conjunctiva. With the progress of inflammation and suppuration the œdema rapidly increased, the eyeball became immobile and displaced forwards, and the conjunctiva was so œdematous that it protruded between the eyelids. On account of the rigidity of the orbital walls the compression and tension were severe, and were contributory factors in the thrombosis of vessels and injury to the orbital contents. The condition was always serious and dangerous, and might terminate in cavernous sinus thrombosis, meningitis, brain abscess, septicæmia, or optic atrophy. Inflammation could extend to the orbit by three paths: by direct spread from the nose through the bone, or along the ethmoidal vessels, by the blood stream when the orbital cellulitis was part of a septicæmia or pyæmia, and by lymphatic spread, but he doubted whether this occurred. In 54 cases of swelling of orbital contents sent him by ophthalmic surgeons for examination of the nose, 24 had suppuration of the frontal sinus and 15 of the ethmoid, 4 were due to injury, 5 had orbital tumour, 2 optic nerve tumour, and there was one each of foreign body with abscess, suppurating cyst, panophthalmitis, and syphilis. The commonest cause in adults was suppuration of the frontal sinus, and in children ethmoidal suppuration. Pus burst through the thin bony floor of the frontal sinus, just to the inner side of the supra-orbital notch, and an orbital abscess was formed between the bone and the orbital periosteum. In a similar way, pus from the ethmoidal cells tracked through the thin os planum or inner wall of the orbit. In some cases the pus was near the foramen of the anterior ethmoidal artery, there was also a second collection in the affected nasal sinus, and both collections must be drained. Injury to the orbital periosteum must be avoided, as it was an effective barrier between the abscess and the delicate orbital contents.

Frontal sinus suppuration involving the orbit produced a downward and outward displacement of the eyeball, and most of the swelling was over the floor of the frontal sinus and at the inner third of the supra-orbital ridge. Ethmoidal suppuration displaced the eyeball outwards. In the majority of cases there were signs of sinus suppuration, and pressure on the external swelling might cause pus to exude into the nose. But a mucocele, which was a closed distension of a nasal sinus, resembled a tumour and might not show signs of inflammation, and in such a case the nose might be normal. A positive skiagram was a valuable confirmation of the diagnosis of sinusitis. When orbital œdema was severe there was reason to fear cavernous sinus thrombosis. In this condition the patient was severely ill with frequent rigors, the œdema was soft and bluish, and extended to the other eye and to the face. Diplopia

on account of paresis of an ocular muscle was an early sign. The pupil was dilated, inactive, and blindness rapidly supervened. It was important to note whether a primary source of infection, such as a boil of the face or middle ear suppuration, was present. Three of the four cases of injury were due to direct blows, and in one of the cases the roof of the orbit was fractured.

Indications of an orbital abscess arising from the nose, were an increasing and brawny œdema of eyelids and conjunctiva, a fixed and displaced eyeball, and excessive pain. Its treatment was always urgent, there should be no hesitation in operating to bring about satisfactory drainage. The cornea must be protected from abrasions, and during the induction of anaesthesia castor oil was dropped into the eye, the eye was closed by means of a stitch passed through the loose skin of the eyelids. A deliberate incision was made along the inner two thirds of the supra-orbital ridge in the line of the eyebrow, and this was carried down below the inner canthus. With the complete arrest of hæmorrhage, gentle retraction and a little dissection enabled the origin of the abscess to be inspected. When a good exposure had been obtained the fistula of the affected sinus was freely enlarged, and the operation was not complete until the suppurating sinus had been attacked from the nose and had been well drained into the latter. He always removed the middle turbinal, and had never had cause to regret this. Of the 37 operated cases 34 had made a rapid recovery and were highly satisfactory. One patient, who had had a previous incision through the upper eyelid, already had meningitis when admitted and died, another died of longitudinal sinus thrombosis. In his series the complications were few.

Dr S H MINGD (Copenhagen) spoke of his experiences in connexion with 86 cases of acute swelling of the orbit, the mortality was 16 per cent. The cause was a sinusitis in 70 cases. The external operation was carried out in 46 cases and 7 died, there were no fatalities, however, in the 24 cases in which the endonasal operation was done. In 46 cases in which sinusitis was verified by operation, the ethmoid alone was involved in 13 and one died, in 5 the frontal alone was affected, with no mortality, in one the maxillary sinus was concerned, in another the sphenoid sinus, and both patients died. In 26 cases two or more sinuses were affected. Often it was difficult, he said, to decide whether a swelling of the orbit was caused by a sinusitis or not, and there was often no history of nasal discharge, aspiration and syringing of the nose might not reveal pus because of a closed empyema. For this reason he had operated even on cases of subperiosteal abscess which had only slight swelling of the mucous membrane, or in which he found pus only in a single ethmoidal cell. Abscess might occur at any age, and there was not necessarily accompanying fever, even in fatal cases. None of the well known signs could be regarded as pathognomonic, and he had come to rely on an examination of the condition of the patient as a whole. Prof Renne had pointed out that in cases of scarlet fever, in which orbital swelling was sometimes very alarming, conservative treatment could nearly always be safely carried out. In the presence of alarming symptoms it was best to operate forthwith as the great danger was eventual intracranial complications. The frontal lobe of the brain being a silent area, indications of these complications might be shown too late. On the slightest suspicious sign, lumbar puncture should be carried out. In children under 5 the frontal sinus was not

usually developed in others he preferred to open not only the ethmoid, but also the frontal sinus.

Mr G H HOWELLS said that the commonest site of the primary infection was the anterior ethmoid. At first there was a pure oedema which had no line of demarcation; hence it was unwise at this stage to embark on any drainage operation as this carried the risk of infecting fresh tissue. Treatment should be as conservative as possible, an attempt being made to drain the sinus by the natural route—namely into the nose, and inhalations, sprays &c were useful. Conservative treatment, if begun early gave considerable prospect of success. It must be realised that surgical complications might arise even after the orbital symptoms had subsided. In cases secondary to osteoma—which might be in the frontal sinus or ethmoid—free drainage through the orbit should first be established, then the offending tumour removed after the subsidence of the acute stage. He had not found it necessary to lose the eyelid by means of a stitch: he had placed a pad of gauze over the eye when operating, and instilled Argylol during convalescence and this he found kept the eye clear. A drainage tube he had always found useful; he brought it down through the nose and kept it in position for four days. The antrum on the affected side was punctured and washed out on alternate days until the washing was clear.

Mr F C W CAPPS said he did not consider a case to have orbital cellulitis unless proptosis was present indicating an abscess. This ruled out cases of oedema of the upper eyelid and supra-orbital region associated with acute sinusitis without true involvement of intra-orbital tissues. While agreeing that supuration was a definite indication for external operation, he could not always feel sure that this had occurred. When in doubt he incised the orbit preferring in these cases the route favoured by ophthalmic surgeons in draining orbital cellulitis leaving the periosteum alone.

The PRESIDENT said that sometimes a small puncture was made in these cases without finding pus but operation revealed that the frontal sinus and ethmoid were full of pus. He spoke of the great change for the better in the outlook of these cases after the use of Prontosil.

Early Bronchiectasis in Children

Dr J H ENNS (Birmingham) read a paper on the relation of early bronchiectasis to ear, nose and throat diseases in children. His material had been gathered from 200 cases: 42.5 per cent of these had gross infection of one or more accessory sinuses and 86.3 per cent had evidence of purulent infection of the middle ear. Whooping cough and measles accounted for a large proportion of the cases of bronchiectasis in children but ulcerative bronchitis and severe bronchio pneumonia were the direct causes. The danger period was the first two years of life; in 360 cases of pneumonia 50 per cent were under two, a third were without symptoms, a third had pulmonary catarrh. The younger the child the more severe was its lung condition: respiratory affections caused more damage in infancy than at any other period. The most important factor in all these cases was infection of the bronchi, and here there was a constant reinfection. But not all cases of bronchitis and pneumonia proceeded to bronchiectasis. The pathology of bronchiectasis pointed to a hope of relief of symptoms, probably to cure if adequate treatment was begun at an early stage. In the chronic stage the only hope lay in removing or destroying the diseased area. Most cases occurred

among children of the poorer classes who had bad homes: there was a great need of more convalescent homes in the country to which these children could be sent. In Switzerland very good results followed short residential treatment and the recognition of the causal connexion of sinus infection with the upper respiratory tract conditions gave real hope for a tangible lowering of the incidence of these diseases in young children.

The Ear, Nose, and Throat in Children's Diseases

Dr BRANFORD MORGAN (Norwich) said that apart from syphilis and tubercle the common infections arose from the upper respiratory and urinary tracts and the skin: the first named vastly preponderating. A simple rhinopharyngitis might suffice to cause refusal of feeds with vomiting and diarrhoea. Authorities had insisted on the almost constant infection of the ears which resulted from nasopharyngitis in the infant in whom the short and wide Eustachian tube provided an easy path for organisms from throat to ear. He paid particular attention to the relationship between gastro-enteritis and ear infections especially to the question whether the ear infection was due to vomitus spreading up the Eustachian tube. Referring to the modern tendency to refrain from treating acute mastoiditis as a surgical emergency he asked whether by postponing the operation the liability to meningial or intracerebral infections was increased. He had recently seen cases in which meningitis had rapidly followed an aural infection and in which on opening the mastoid comparatively slight disease was found. A number of children brought to hospital because they were constantly catching cold had allergic rhinitis and some had a latent infection of the sinuses: their temperature was raised with headache and a feeling of stuffiness. These symptoms abated when free drainage was instituted.

Tuberculous Ulcerations of Mouth and Pharynx

Mr F C ORMEROD said that when the tonsils and fauces were affected with tuberculous the outlook was always grave and a fatal termination could be expected in two or three months. Tuberculous disease of the tongue however was a more curable disease and the life of the patient with this was considerably longer than with faucial tubercle. When the floor of the mouth, the gums, and lips were involved the outlook was definitely more serious. Of 17,000 cases of ulceration referred to the throat department at Brompton Hospital 12,000 were tuberculous and in the same time there were 3,120 cases of tuberculosis of the larynx, 20 of the tonsil, 32 of the pharynx, 20 of the tongue, 4 of the post-nasal space, 2 of the lips. The age of attack in mouth and pharynx cases was slightly younger than in tubercle of the larynx—namely 20-30 as against 30-40. Tuberculous disease in pharynx and mouth was nearly always a complication of very severe disease in the lung: it could often be taken as a sign that the patient's resistance to tubercle was breaking down. The chief symptom in the pharyngeal cases was the extreme pain, the difficulty in swallowing and the distressing quantity of saliva formed which the patient was constantly feeling the impulse to swallow though it was such a painful process. An exceedingly serious type of lesion was ulceration of the posterior pharyngeal wall. In some cases this extended upward into the post-nasal space and laterally on to the posterior pillar of the fauces so that whatever the patient ate or drank

it was impossible to steer the food clear of an ulcerated area, and unless some remedial measure was carried out death from starvation might take place. In most of these cases the prognosis was very bad. It was useless to attempt to treat these cases as out-patients, they required thoracoplasty, or paralysis of nerve, or artificial pneumothorax, or at least sanatorium treatment. The best local measure was diathermy, carried out under cocaine anaesthesia, in many cases this enabled comfortable swallowing to be carried out for a time.

At the meeting of the section of otology, presided over by Dr DOUGLAS GUTHRIE, a paper on some

Problems of Aural Medicine

by Dr MYGIND and Dr DIDA DEDERDING was read by the former. The treatment of the non surgical diseases of the ear, he said, had not got far beyond the catheterisation of the Eustachian tube of 200 years ago. This was possibly due to the dramatic evolution of aural surgery, but perhaps in part, too, to an erroneous conception of the localisation and nature of a series of non suppurative ear diseases. The usual interpretation of the findings from acoustic tests needed revision. Perception deafness was characterised by a lowering of the upper limit, but only if there was a lowering by bone conduction as well as by air. Hearing of the high-pitched whispered voice was more severely impaired than the hearing of the low-pitched conversational voice. On the other hand, sound conducting deafness was characterised, in the first place, by an elevation of the lower limit, the upper limit in the less severe cases being preserved. The double testing of upper limit of hearing by air and by bone became the best method of distinguishing between a sound conducting and a sound perceiving affection. In 721 cases 89 per cent had a sound-conducting affection, 3 per cent were defective in sound perception, and in 8 per cent there was a combination of the two. His colleague's and his own investigations had shown no sharp line of separation between affections of middle ear and those of the labyrinth. On examining cases of so-called neuro-labyrinthitis the cochlear nerve was found to be intact, the labyrinth was affected, as shown by vestibular signs and frequent tinnitus, but the lesion was localised peripherally to the perceiving organ itself, the middle ear was also involved. Many cases of apparently ordinary tubal stenosis or middle ear catarrh were accompanied by labyrinthine symptoms, not only tinnitus, but also vertigo and nystagmus. He was convinced that both

in Mérière's disease and many other sound conducting affections one was dealing with a disturbance of the vascular function, especially in the capillaries. As a result there was a hydropic swelling of the inadequately nourished cells. If such a patient were dehydrated, either by excessive perspiration, or by diuretics, his hearing would be found to improve. The ear was often found to be the site of a morning oedema, which wore off during the day's activities. The object of the paper was to present an explanation based on clinical, anatomical, and physiological phenomena for conditions found not only in the ear but in all parts of the body, the prime causal agent being vascular. The object to aim at in treatment was to tram by stimulation the capillaries of skin, muscles, and lungs to a higher capacity.

Dr PHYLIS KERRIDGE read a paper and gave gramophone demonstrations on

Hearing and Speech in Deaf Children

She had been instrumental in testing the hearing of 500 children in schools for the deaf in London by means of the pure tone audiometer, and in some cases by other means also, so that methods could be compared. This capacity or incapacity was correlated with the intelligence, the age, and other factors. As a result it was estimated that three fourths of the children in schools for the deaf would benefit from the use of suitable sound magnification instruments. The hearing power of the children by air and by bone conduction was tested at eight pitches, and the results correlated with the medical history and the degree of speech proficiency.

Mr HAMBLETON THOMAS, in a paper on the

Physical Aspects of Tinnitus

defined tinnitus as the response of the auditory part of the 8th nerve to abnormal stimuli. The causes of this were many, and little accurate information was available as to what they were. Causes could be classed as either extrinsic (arising outside the ear) or intrinsic. The former included muscle movements outside, and sounds coming through the Eustachian tube. Intrinsic causes included vascular conditions and hyperaesthesia of the 8th nerve, and perhaps the abnormal action of currents. Whatever might be discovered in respect of physical causes of tinnitus was likely to be of help in these distressing cases, which were sometimes so severe that the patients committed or attempted suicide.

During Friday afternoon some twenty cases were inspected and discussed, and in the evening members dined together.

NEW INVENTIONS

AN IMPROVED AND INEXPENSIVE CULTURE BOTTLE FOR THE PREPARATION OF VACCINES

Roux bottles have almost completely replaced other forms of culture bottles when a solid medium is used, particularly in the preparation of vaccines. The ordinary type have, however, a number of disadvantages—

Firstly they are expensive, varying in price from 27s to 35s per dozen. The cheaper varieties rely entirely on the thickness of the glass for their heat resistant properties and in consequence are extremely fragile, they have to be handled with the greatest of care and there is the attendant risk. It has therefore been safer and more economical to use the stouter but more expensive varieties

Secondly the mouth requires to be plugged, and when vaccines are being made on a large scale this occupies much time.

Thirdly, the agar is inclined to slip in the bottles, so it has become customary to incubate them lying flat with the agar lined side downwards and the growing surface of the agar pointing upwards. This is not good practice, for water condenses on the upper and inner wall of the bottle in large drops which eventually fall on the surface of the agar below. The constant drip damages the surface of the agar and results in some agar being retained in the suspension when the growth is eventually washed off. This can be avoided to some extent by giving the bottles a slope while they are being incubated, but even so slipping of the agar is likely to occur. The retention of even small quantities of agar in the finished vaccine is in my opinion one of the most potent causes of those severe reactions to T & B C vaccine that are occasionally experienced.

It was considered therefore that some sort of screw cap bottle might be used with advantage. To have such a bottle made was out of the question as the cost would have been prohibitive. Accordingly experiments were made with various types of bottles available commercially. Of those tried a bottle made by the United Glass Bottle Manufacturing Co. London and catalogued by them as bowl panel 32 oz. was found to be very satisfactory and the cost is only 4s. per gross.

This bottle measures 8½ in. from bottom to shoulder is 4 in. wide and 1½ in. deep. The bottom is flat externally and has a low convex surface internally. One side of the bottle is flat and the other low concave-convex from within outwards. On the flat side externally there is an oblong depressed area which corresponds to a raised area on its internal surface. This peculiarly indented panel together with the convex internal surface of the bottom holds the agar firmly after it has set. The neck of the bottle is 1½ in. long and the mouth has an internal diameter of 1 in. which is covered with an aluminium screw cap. As supplied by the manufacturers this cap is fitted with a cork and grease paper washer.

The whole bottle is constructed stoutly of clear glass through which any medium inside the bottle and the characteristics of any growth on such can be easily seen. The figure shows the internal and external characteristics.

METHOD OF USE

The cork and grease paper washer must be removed from the aluminium cap and replaced by one of rubber. The bottle is thoroughly washed with soft soap solution, rinsed with tap water then with distilled water and sterilised in the autoclave at 120° C. for 1 hour. While being sterilised the screw cap is in position but not screwed.

tight. After sterilisation 130 c.c.m. of sterile agar is poured into the bottle and autoclaved at 115° C. for 20 minutes. The bottle is then laid on the bench flat side downwards on an incline of about 3° so as to give the agar a slight slope from the bottom towards the neck and the cap is screwed down tight. The screw cap with its rubber washer prevents any evaporation of the water of condensation &c. and media can be stored ready for use in these bottles for short periods without fear of deterioration from this cause. After the agar has set each bottle is incubated for 24 hours at 37° C. as a test for sterility. While being incubated they are placed in the incubator so that the flat agar-lined side is uppermost. The surface of the agar is available for growth in these bottles is equivalent to four fifths of that obtained in a Roux bottle of 1000 c.c.m. capacity. By using a two way metal screw cap fitting similar to that employed by McCartney¹ by means of which air can be withdrawn and replaced by CO₂ or any other gas that may be desired, these bottles can be adapted for the culture of micro-aerophilic organisms &c.

These bottles have certain disadvantages. They are heavy and they cannot be sterilised in the hot air oven. It might be thought that the airtight fitting screw cap would lead to such a deficiency of oxygen in the bottle in the presence of rapidly growing aerobic organisms that a poorer growth of these organisms would result. It was found that in actual practice where only 24 hour cultures are used for vaccines, this was not the case and indeed heavier suspensions were obtained per square cm. of growing surface than from the Roux bottle. These bottles have been put through an extensive trial at the Medical School Royal Naval College Greenwich and have been employed in the preparation of 70 000 c.c.m. of T.A.B.C. vaccine. During this period 420 of these bottles were used and in no instance was trouble experienced with slipped agar. These bottles can be obtained fitted with aluminium caps and rubber washers ready for use from A. Gallenkamp and Co. Ltd. London.

REVIEWS AND NOTICES OF BOOKS

A Manual of Radiological Diagnosis

By IVAN C. C. TCHAPEROFF, M.A. M.D. D.M.R.E.
Camb. Assistant Radiologist and Radium Registrar
St. Thomas's Hospital, London. Cambridge
W. Heffer and Sons, 1937. Pp. 250. 21s.

In this book Dr. Tchaperoff has attempted with considerable success to set out clearly the typical radiological appearance of any disease so that rapid reference can be made to it. The work will thus be useful not only to the student preparing for examination but to the busy radiologist wishing to refresh his knowledge of a particular lesion. In the scope afforded by 250 pages the reader will not expect to find full descriptions of the rarer abnormalities, but he must be prepared for certain omissions of more consequence. Fractures are only very briefly considered; there are only two lipiodol pictures of the chest and no arteriograms. It is disappointing also to find no pictures of ulcer deformities of the duodenum and in the last chapter (3 pages) on tumours of the spinal cord and ventricles only one abnormal ventriculogram.

The work is well planned. In the introductory chapters the author refers to several technical points which will help the inexperienced reader to interpret films. In each section of the book a description of the normal appearances precedes discussion of

the various pathological appearances recognised also by X-ray examination. The differential diagnosis is outlined with the description of the lesion. Each section is freely illustrated and the abnormalities in the radiograms are clearly demonstrated by numbers. The book is a practical addition to radiological literature.

The Morphine Habit and Its Painless Treatment

Second edition. By G. LAUGHTON SCOTT, M.R.C.S.
B.A. Oxon., late Senior Physician, London Neurological Clinic, late Chief Assistant, Guy's Hospital.
Neurological Department, London. H. K. Lewis and Co. 1937. 1p. 10s. 6s.

Dr. Laughton Scott's method of treatment of morphine addiction consists of covering the gradual withdrawal of the drug by means of increasing doses of belladonna. In this second edition of his book he has introduced a brief discussion on the physiology of this method of treatment. He points out that the effect of morphine upon the addict is to stimulate the vagus, while its narcotic action tends to disappear. Consequently a shortage of supplies of the drug means the diminution of vagal control and sympathetic overaction. The physiological effect of treatment therefore is to reverse the disturbance

of autonomic balance by increasing doses of bella donna, a drug which, given in this way, exercises a stimulating, instead of its usual depressing, effect upon the vagus. Dr Scott describes his technique in detail, particularly emphasising the importance of careful management during convalescence, which is essential to prevent relapse. He contrasts the absence of shock associated with this method, which has given excellent results in his hands, with the effect of older and more drastic methods. He does not, however, describe treatment with insulin, which is employed with a similar effect upon autonomic balance, nor the use of the drug "rosum" for which good results have been claimed, especially in the United States. This book will undoubtedly be useful to those faced with the difficult task of treating morphine addiction.

When Temperaments Clash

By MURDO MACKENZIE, M.D., M.R.C.P., Physician for Psychological Medicine, St John's Hospital, Lewisham, and the Wilson Hospital, Mitcham. London: Thos Murby and Co. 1937. Pp. 227. 7s. 6d.

This small book deals in a non technical manner with the subject of "nerves" and seeks to describe the symptoms and to explain the causes of this modern curse. The early chapters contain an account of neuronic instability and the resulting "anxiety-apathy cycle," with examples drawn from everyday experience. Later Dr Mackenzie discusses in detail the fundamental components of temperament, pace, and sense of value, and holds that everyone is by natural bias a craftsman, an advertiser, a dealer, or an administrator according to whether his pace is deliberate or immediate and his sense of value one of simplification or of amplification. Neuronic instability results when the individual's natural bias, through ignorance or compulsion, is prevented from acting freely and is used in defence instead of for progress, and when, instead of co-operating with the opposite temperaments with which he comes in contact, he clashes with them. To make the most of his natural bias, the individual must consciously or unconsciously know what it is and must be able to release it to the full.

The book is presumably intended mainly for the layman and probably for this reason Dr Mackenzie is inclined to repeat his arguments and to multiply his instances to what may seem an unnecessary extent, perhaps thereby showing that his natural bias is towards amplification rather than towards simplification, but apart from this defect, the medical reader will find much of interest and value in its explanation of common problems.

Latent Syphilis

And the Autonomic Nervous System. Second edition. By GRIFFITH EVANS, D.M. Oxon, F.R.C.S., D.O.M.S., formerly Hon Surgeon, Caernarvonshire and Anglesey Infirmary. Bristol: John Wright and Sons. 1937. Pp. 158. 7s. 6d.

Mr Griffith Evans's work is based upon the belief that the diagnosis of syphilis ought not to be restricted to those cases which satisfy one of the three customary criteria—namely (1) the Wassermann test, (2) demonstration of spirochaetes, (3) gross pathologic lesions. It is not altogether clear what are his further diagnostic criteria, but his views on the importance of syphilis in the etiology of many disorders are indicated in a table which shows that

syphilis is responsible for 27 per cent of cases of "blanching of the extremities," over 30 per cent of cases of diseases of the thyroid and of asthma, 63 per cent of cases of "congestion of the extremities," and 100 per cent of (six) cases of purpura. Syphilis appears also, in his view, to be an important cause of "the chronic abdomen" and of cancer. Osler once said that if you know syphilis, you know clinical medicine. Mr Evans seems to regard the two as identical.

Canning Practice and Control

By OSMAN JONES, F.I.C., Chief Chemist, C and T Harris (Calne) Ltd., and T. W. JONES, B.Sc., Editor the *Industrial Chemist* and *Food*. London: Chapman and Hall. 1937. Pp. 254. 25s.

CANNING in this book is limited to foodstuffs put up in metal containers. In their preface the authors describe it as a bench book and their aim is to make it of practical value to the canner. In this object they have succeeded, but a large part of the book is a technical treatise which will appeal also to the works chemist. About 87 pages deal with factory and mechanical questions while more purely laboratory matters occupy about 131 pages.

On the practical factory side the authors deal very comprehensively with their subject. The chapter on the cannery and its equipment is a good illustration of its quality. This chapter deals, amongst other things, with single versus multi storeys, the position of the factory, and the mechanical equipment. The location in country or town depends a good deal upon the nature of the food to be canned. The requirements of each type of food canned are considered separately. Such important matters as the type and size of can, the nature of the tinplate, and the use of lacquer are discussed. The important question of lacquer might have received more comprehensive treatment with advantage. Rather more space might have been devoted to the life of canned foods. On the other hand an excellent account is given of "hydrogen swell." Cannery waste and cannery hygiene are treated in separate chapters. The effect of canning upon nutritive values is discussed in rather a tentative way, as the authors point out our knowledge on this aspect of the subject is still far from complete.

The chemical, bacteriological, and microbiological aspects are dealt with in considerable detail. Indeed some questions, such as the ordinary chemical examination methods for water, might have been omitted with advantage as they are so fully described in the ordinary text books on the subject. The more technical matters which specially apply to canned foods, such as testing for leaks, tinplate examination, metallic contamination, and the detailed examination of the raw food products, are all adequately considered. On the bacteriological side the authors do not seem quite decided as to the significance of aerobic spore contamination and in holding that these are causes of spoilage hold views not in accord with those of most bacteriologists. The treatment of *B. botulinus* in relation to canned foods omits much of value and in view of its great importance should have received much ampler treatment.

On the whole the volume is likely to be of great practical utility and should help to make canning a less empirical and a more scientific procedure. It should be of material service both to the food canner and to the technical experts associated with the manufacturer.

THE LANCET

LONDON SATURDAY JUNE 26 1937

THE GENERAL REGISTER OFFICE, 1837-1937

IN the publicity attending the centenary of the General Register Office much has been heard of marriage registers something of census taking and a little a very little of medical statistics. In this office our thoughts turn naturally to the romance of medical statistics rather than to that of the Fleet and Mint registers of marriages (now we understand in the custody of the General Register Office) because had it not been for the founder of THE LANCET we might not now be celebrating a medical-statistical centenary. On June 29th 1839 we published a leading article on the first report of the Registrar General. Its writer said:

'Magendie has starved rabbits poisoned dogs cut their nerves drained their veins and investigated the effects of reagents upon their blood—thousands of frogs and cats sparrows chickens and mice geese pigeons and turtles have been sacrificed not cruelly—not to gratify carnivorous propensities—not to seek superstitious indications—but in the hope of surprising the mysteries and laws of vitality. The Lecturer of the College of France in the plenitude of his zeal would however never think of rendering men the subjects of his experimental crucifixions. But continues the writer, 'in the present state of society are not the experiments from which the physiologist would shrink—and which he would not dare to name or which he would not think of proposing performed upon a large scale? What variety of occupation and exercise can the experimentalist require that is not practised upon the hills and the plains in the factories and the potteries under the earth and on the seas? And must it be that because we can only observe these phenomena and cannot experiment that they are to be neglected? One sees to what this is tending and how it must have rejoiced the heart of young Mr FARR. Indeed as there are two Latin quotations a reference to augurs and to men of such widely different celebrity as MAGENDIE and UNIC one might even conjecture that—but we need not do so. Anyhow the founder of THE LANCET believed in Farr and said in the very next issue. The pages of this Journal have frequently been enriched by statistical contributions of Mr Farr and we feel much pleasure in recording our approbation of the article now before us which cannot fail to lay a lasting foundation of honour for its learned author.

Indeed we may fairly look upon Farr's career with some parental pride. In our columns he commenced author we rejoiced in his later achievements over the way in which he really did drive home to the sanitarian the lessons to be learned from experiments in the factories and the potteries

the results of which were recorded in the registers. Perhaps we might even claim that Farr's association with journalism served him well. Nicely educated young men of this age who eschew superlatives true blue civil servants whose principles forbid them to come nearer the crudity of 'I think' than is expressed by 'it may perhaps be thought' find Farr a trifle flamboyant. But nobody could find him dull. The belief that medical statistics are dull reading will not we hope survive Dr BRADFORD HILLS's book. Anybody needing further reassurance should turn over Annual Reports of the Registrar General in Farr's time. One of the last of his 'Letters to the Registrar General on the Causes of Death' that for 1876 contains an essay on that topical subject maternal mortality. From the statistical and historical point of view it is profitable reading. In collecting materials for his statistical study Farr had perused the details of individual cases. There was one of a death from flooding due it would seem to the practitioners' negligence. Farr obtained and printed a moving letter from the dead woman's husband. A prudent official would have left it without comment or at most have added 'it is perhaps to be regretted that'. But the old journalist's blood was stirred and he wrote. In recollecting her pale lips and blanched cheeks as she lay the tears rushed to her father's eyes.

In questa forma

Passa la bella donna e par che dorma

Such fearful cases should be judged by the Medical Council.

Farr's genius made medical statistics a science. His training helped him to make others share in human sorrows the events of which were merged into averages. Carefully avoiding a Latin quotation which he would surely have made we will say that Farr was never in any danger of forgetting in statistical analysis the real object of collecting statistics. The work he began has grown so great that whether we like it or not idiosyncracies of expression however charming must be eliminated from official documents. Now it is for the readers not for the compilers of official medical statistics to realise what is behind these scribbled ranks of numbers.

- BLOOD TRANSFUSION

It is now about twenty years since transfusion was established on a sound basis and became an accepted part of medical and surgical routine. No figures are available for the number of transfusions yearly performed in this country but it must run into many thousands and is rapidly increasing. In 1921—the year of its inception—the London Blood Transfusion Service arranged a donor for 1 transfusion. By 1931 the number had risen to 2078 and this year it will probably prove to be more than three times greater. For the country as a whole the increase is probably very similar. But whereas the needs of London have been admirably met by the comprehensive service directed by Mr P. L. OLIVER the provision of donors in other districts has usually had to be

organised by individual hospitals. The work is apt to devolve upon the hospital's pathologist, and any who have to start or control such a service will find valuable ideas in Dr S C DYKE's account of the one established at the Royal Hospital, Wolverhampton, which appears on p 1538. This service was organised for the hospital, and is maintained free of charge to it, by the Wolverhampton Rotary and Round Table Clubs which thus put into effect their motto "service for all". The example has already been followed by other rotary and round table clubs both in this country and abroad and deserves further emulation.

It is a pleasant fact that donors are seldom lacking when urgently required, but even with the most perfect organisation the delivery of blood by donors in their own person entails difficulties and inconvenience, and it would obviously be a great advantage if suitable blood could be stored for use as required. At the Hastings meeting of the Association of Clinical Pathologists, reported on p 1523, various speakers recorded experience pointing to the conclusion that untoward reactions are to be expected after the use for infusion of blood stored under ordinary ice-box conditions for more than a week, but far more information on the subject should soon be available from Russia and from Spain, where stored blood is widely used. Much of the blood used in Spain, apparently with success, is stored under a positive pressure of two atmospheres.¹ Dr J O OLIVER, of St Thomas's Hospital, reported that by bubbling oxygen through stored blood he had been able to keep it in a state suitable for infusion for at least a fortnight, and the question arises whether the oxygen tension may not be the determining factor in the preservation of the blood for infusion. Of more immediate interest to most of us, however, is the continuing possibility of "reactions" after transfusion of fresh blood, leaving aside those due to gross incompatibility. In the past there has been too great a tendency to regard these as necessary evils. In Russia, where transfusion is largely practised, reactions appear to be both frequent and severe. BOGOMOLETZ² attributes them to a mysterious process of "colloidoclasia" in the infused serum, and thinks them more or less inevitable. His paper is largely a statement of this view, which appears to be orthodox in Russia, and a polemic against HESSE and FILATOV, both recent immigrants into the Soviet Union, by whom the reactions are attributed to errors in technique such as chilling of the infused blood, improper preparation of solutions used, and lack of cleanliness in the apparatus. This view is hotly contested by BOGOMOLETZ, but most workers in this country will agree with HESSE and FILATOV. As Dr JANET VAUGHAN pointed out in the course of the discussion at the Hastings meeting, many transfusions are performed very casually. To secure such attention to detail as is required to ensure a perfect technique, Dr DYKE believes that the whole transfusion service of a hospital

should be the responsibility of one person, preferably a senior resident officer, and he reports that since this has been done at the Royal Hospital, Wolverhampton, reactions after transfusion have almost disappeared. It is worth pointing out that the importance of avoiding the chilling of infused blood is now so well recognised that in skirting Scylla some have been dragged into Charybdis. Only a week or two ago Prof S L BAKER recorded in our own columns³ a death following infusion of overheated blood.

The number of transfusions given increases by leaps and bounds, but are they all really required? The general opinion at the Hastings meeting was that they are not, and there can be little doubt that many patients are given blood that would have been far more useful to others. The primary indication for infusion of blood is to replace blood lost by hæmorrhage. Sudden loss of blood, to an extent that will not cause dangerous exsanguination, is often followed by a degree of "shock" and many transfusions are performed for such shock where the actual loss of blood is not serious. It is increasingly clear that such patients, though they need fluid, do well—perhaps better—without transfusion. It is also questionable how far it is useful to transfuse blood in the so called idiopathic anæmias with a view to stimulating the hæmopoietic system, but here at least there is little likelihood of doing harm. Transfusion is likewise often employed in acute and even chronic septic states, and here again its value is doubtful. Finally, it is used by no means seldom because things are desperate and transfusion seems a good sort of thing to do. Clearly there is room for much better definition of its appropriate application.

NEUTRALISING ANTIBODY IN POLIOMYELITIS

THERE is ample evidence that virus infections, whether natural or experimental, call forth specific antibodies just as bacterial diseases do. The relation of these antibodies to immunity has been closely studied and it is generally agreed that in many virus infections, at any rate, they play an important part, the practical application of this is seen in the passive prophylaxis of a disease like measles. It was thought at one time that infection with the virus of poliomyelitis gave rise to the production of specific viricidal antibody which was necessary for combating the infection and preventing reinfection, indeed it was on this assumption that convalescent serum was used in the hope of arresting the infection at an early (preparalytic) stage. The fact that the serum of many adults who have never suffered from poliomyelitis contains antibody has been attributed to subclinical infection, just as the majority of adults, especially in our urban populations, acquire diphtheria antitoxin without having ever had manifest diphtheria, so also they might acquire poliomyelitis antibodies through mild unrecognised attacks of the disease.

¹ See *Lancet* June 5th 1937 p 1359.

² Bogomoletz A. *Journal médical (Acad. des Sciences de la R.S.S. d'Ukraine. Inst. de Physiol. clin.)* 1937, 7, 16.

³ Baker S L. *Lancet*, June 12th 1937 p 1399.

During the past few years however, evidence has been accumulating which suggests that the happenings in poliomyelitis are not in accord with this orthodox belief. The therapeutic use of convalescent serum, despite earlier favourable reports is now looked on with scepticism by the majority. This change of front has been due to the negative clinical results obtained in America by PARK and his colleagues¹ and also to a better understanding of the route by which the virus of poliomyelitis reaches the susceptible cells in the central nervous system. The apparent failure of convalescent serum to affect the course of the disease is not surprising if it is accepted that the virus infects via the olfactory nerves—which it reaches either by way of the olfactory hairs or the olfactory cells—and that its spread thence to the susceptible cells in the central nervous system is axonal for from the very earliest stage of infection the virus is intracellular and therefore protected against specific antibody. The idea that antibody is unimportant in resistance to infection with poliomyelitis virus finds further support in the experimental work of SCHULTZ and GERHARDT² who have shown that the monkey passively immunised and possessing adequate circulating antibody is little less susceptible to infection by the nasal route than the normal animal. Fresh information is now provided in a paper by BRODIE, FISCHER and STILLERMAN,³ recording their observations on the incidence of neutralising antibody in poliomyelitis. They tested for antibody by intracerebral inoculation in monkeys of serum virus mixtures two strains of virus being employed a monkey passage strain and a recently isolated human strain. Their investigations failed to show any relationship between the presence of antibody in the blood and resistance to or recovery from infection. Antibody was found in the acute stage of the disease in 32 out of 114 cases—in 2

of these the serum was obtained in the pre-paralytic stage of the disease—and out of 39 patients with residual paralysis who had had no protective substances in their blood in the acute stage of the disease only 2 developed antibody during 12–16 months observation.

Observations like these reported by BRODIE and his colleagues have been made before by others and it appears that neutralising antibody may be present early in the disease probably before its onset and that infection often fails either to influence the titre of pre-existing antibody or to evoke its production in those in whom it is initially absent. From what has already been said about the route of infection followed by this virus it is understandable that the presence of neutralising antibody should be without much influence either on the incidence or the course of infection. What is rather disturbing is the complete lack of correlation between infection and the development of antibody. As we have said, this is not the first time that the discrepancy has been noted and it has led some workers to doubt the specific nature of the neutralising antibody and to suggest that its development is the outcome of physiological activities.⁴ The problem is of course not confined to poliomyelitis for we are faced with a similar difficulty in the interpretation of the origin and significance of the so-called normal antibodies. Are these the result of infection or is some other mechanism responsible for them? The evidence available does not allow of a definite answer but for the time being it would perhaps be a mistake too readily to abandon the orthodox view. As far as poliomyelitis is concerned might not antibody be merely a by-product of infection the response to that variable amount of virus which gains access to tissues other than those of the central nervous system? This might account for the irregularity of its development. Meanwhile however, we remain in ignorance of the mechanism of immunity to poliomyelitis.

ANNOTATIONS

PSEUDO-METHAEMOGLOBIN

ELSEWHERE in this issue in a report on p. 1523 brief mention is made of a paper read by Dr Hamilton Fairley to the Association of Clinical Pathologists describing the occurrence of pseudo methaemoglobin in blackwater fever. Dr Fairley and Dr J. I. Bromfield made a further communication on the same subject to the Royal Society of Tropical Medicine and Hygiene on June 17th. Quite apart from their bearing on blackwater fever the observations now reported appear fundamental to the understanding of haemoglobin metabolism. Like all real advances in science they raise many new and exciting problems.

In 1931 Fairley and Bromfield first noted in the plasma of a patient suffering from blackwater fever a previously unrecognised pigment closely related to methaemoglobin but differing from it. This pigment produced a chocolate coloured blood with a brown plasma; it was absent from washed corpuscles

and did not appear in the urine. Prof David Keilin to whom the pigment was sent regarded it as a modification of methaemoglobin in which the globin portion of the molecule had been altered undergoing some irreversible change. Its spectrum has the general appearance of methaemoglobin but the bands are shifted about 60 Angström units towards the short wave end of the spectrum and it has none of the properties of methaemoglobin when tested with Stokess reagent or ammonium sulphide. Recently Fairley and Bromfield have continued their investigations on a large group of cases of blackwater fever in Macedonia a country which might from their accounts be described as the haematologist's paradise. They found this new pigment which they have named pseudo methaemoglobin constantly present in the plasma in all severe cases of blackwater fever. In the past it has been mistaken for methaemoglobin. It is never found in corpuscles and is apparently formed from oxyhaemoglobin only after its liberation

from the red blood cells. The investigators were able to produce it *in vitro* by incubating solutions of oxyhæmoglobin, methæmoglobin, or sulphæmoglobin at 40°C for 24 hours or longer in the presence of sterile plasma. They believe that it is in no way peculiar to blackwater fever, but will probably be found in the serum in any condition in which there is sudden severe hæmolytic, such as cold hæmoglobinuria, possibly acute hæmolytic anæmias, and in incompatible blood transfusions. It does not appear in the urine. Methæmoglobinuria is common in blackwater fever, but the methæmoglobin is derived from oxyhæmoglobin after it has traversed the glomeruli and does not result from methæmoglobinæmia. It is known that the presence of large amounts of oxyhæmoglobin in the plasma leads to serious renal damage with injury of the renal tubules due to precipitated pigment and consequent anuria and often death. Farley and Bromfield suggest therefore that the conversion of free oxyhæmoglobin into pseudo methæmoglobin is to be regarded as a conservative action on the part of the body, since pseudo methæmoglobin does not itself pass through the kidneys and in its formation reduces the amount of oxyhæmoglobin available to damage these organs. This reaction, they suggest, is the first stage in a hitherto unrecognised mechanism by which the body disposes of circulating extracorporeal blood pigment. Why the cells in blackwater fever are hæmolyzed is still not known. What property or factor in the plasma induces the formation of pseudo methæmoglobin remains to be discovered. Why in some patients oxyhæmoglobin is not converted into the less dangerous pseudo methæmoglobin in sufficient quantity or with sufficient speed to prevent renal damage is also not known. As Farley himself suggested, the recognition of this mechanism opens up the possibility that a drug may be found that will convert oxyhæmoglobin into the more harmless pigment when the body's own processes fail.

Many must have felt as they listened to Dr Farley that he and Dr Bromfield with a company of hæmatologists should pack their bags at once for Macedonia to try to answer some of the questions their work has raised.

COMPATIBLES IN THE MENU

Few doctors in this country can have escaped being asked at some time or another what they think of the Hay diet. The questioner is more often an acquaintance than a patient, and the question casual rather than serious, for the person who intends to follow directions given in his newspaper does not want to hear his regular medical adviser say that these are unreasonable. Dr W. H. Hay and his business associates have shown, if nothing else, that there are a great many people who can readily be persuaded to follow such directions, with suitable assistance one simple idea can be made to go a very long way. Dr Hay's idea—or, as some call it, a bugaboo—is that carbohydrates and proteins should not be eaten at the same meal, because protein (he says) increases the gastric secretion of acid and so hinders the digestion of starch by the saliva. The delayed digestion of carbohydrate is supposed to allow fermentation to take place and the acids (of secretion and fermentation) are absorbed into the circulation, causing almost every known ailment and eventually death. This month Dr Eugene Foldes² of New York has demonstrated how completely experience and

experiment contradict this theory. The amount of hydrochloric acid secreted after taking carbohydrates is not very different from the amount secreted after taking proteins. Even if there were a significant difference an increased amount of hydrochloric acid in the stomach would not wholly interrupt starch digestion, and even if it did so, fermentation in the stomach would not follow. If there were any fermentation it would be in the intestines rather than the stomach, and it would not lead to the production of significant quantities of acid, nor is there any reason to believe that the body would be unable to cope with such acids even if they formed in larger quantities. So far then there is no evidence to substantiate the theory. Against it are the intimate mixture of protein and carbohydrate in many natural foods, the fact that contents of the stomach ferment only where there is achlorhydria, and the comparative harmlessness of "acids" in a ketogenic diet except in one or two well defined conditions like diabetic coma. The chief danger run by followers of the Hay diet is that they may reduce the protein in their daily ration unsuitably.

THE BLOOD AT HIGH ALTITUDES

Krupski and Almasy¹ have been studying the influence of high altitude on the physiology of the blood. The material of their research consisted of two men aged 45 and 33, two women both aged 25, a bull calf aged 4 months, and a goat aged 6 years. These spent 83 days at Zurich, 19 days on the Jungfrauoch (11,200 feet), and 27 days again at Zurich. Like other workers, Krupski and Almasy found that the rise in altitude brought an increase in the red blood cells, not exceeding 15 per cent. The maximum increase for the four volunteers and the goat was in the second and third week, for the calf it was in the first week. The human beings also showed individual differences. On going down into the valley the red cell counts returned to normal. The reticulocyte count increased during the first week's residence at high altitude and diminished during the second week. An important fact was that the maximum amount of hæmoglobin in all four persons was reached during the second week they remained at a height—that is, at a time when the reticulocyte count had already decreased. In the calf and the goat no reticulocytes were observed in any of the three periods, but this is not interpreted as meaning that there was no increase in bone marrow activity. The number of leucocytes was hardly changed at a high altitude, but a decrease of lymphocytes was noteworthy and all investigators are agreed on an increase of neutrophils, such as Hartmann discovered at over 10,000 feet in the Himalayas. The Jungfrauoch counts showed neutrophil lymphocyte ratios different from those described by Hartmann at the same altitude. At the high altitude the calf and the goat had no diminution of lymphocytes, but a relative increase of neutrophils. (A high lymphocyte count is normal in goats and cattle.) A slight increase of monocytes was noticed in three of the human beings and the two animals. During the residence on the Jungfrauoch hardly any deviation from the normal was apparent in eosinophils and basophils. This corresponds with Hartmann's observations. Serum of both the animals showed a negative bilirubin reaction (Ehrlich-Proschner) not only in the valley but also at a height and even after considerable reduction of the erythrocyte count in the third period.

¹ Krupski A. and Almasy, F. *Helv. med. Acta* February, 1937 p. 94.

at Zurich. Determination of the dry substance of the plasma showed that the changes in the red blood-cell count are seldom due to loss of water from the plasma.

The comparison of oxygen capacity with carbon monoxide capacity of normal blood used for the determination of hemoglobin showed agreement. The oxygen capacity is normally proportionate to the red blood-cell count, any deviation from this being expressed in the average oxygen capacity per erythrocyte (SKE=Sauerstoffkapazität pro Erythrozyt). In the valley when the red blood-cell count was raised SKE diminished and vice versa on the Jungfrauoch when the red cells rose SKE rose too. The influence of intensive walking exercise at medium and at high altitudes was investigated on three occasions in one individual. The number of leucocytes was much increased on two of the expeditions and on the third remained unaltered. It is to be noted that there was a decrease of lymphocytes and an increase of neutrophils. On the third expedition after 14 days at high altitude and five hours strenuous exercise there was no definite increase of reticulocytes.

Authorities do not agree about the effects of the altitude on the oxyhemoglobin absorption bands seen in spectroscopy of the blood but during residence on the Jungfrauoch the oxyhemoglobin absorption bands almost always showed an increase both in humans and in animals.

MEDICAL PROTECTION

THERE should be no need to harp upon the advisability of joining a professional defence society. Membership has become particularly important since the passing of the Law Reform (Miscellaneous Provisions) Act of 1934 whereby the estate of a deceased person may now be made liable to claims based on some act or fault during his life time. Whether or not the sponsors of this so-called law reform intended merely to give a remedy to the victims of fatal accidents in "running down" actions the recent case of *Rubra v. Connolly* has shown that the widow of a doctor may be adjudged liable to pay heavy damages out of his estate for some alleged default by her dead husband in the course of his practice. The medical defence societies have consequently been extending their benefits so as to give the personal representatives of a deceased member all such privileges as would have been available if the member were still alive.

The report of the London and Counties Medical Protection Society presented at the annual meeting on June 10th rightly draws attention to this new risk of practice. In addition it repeats much salutary advice of a general kind. Members in their own interests should refer matters immediately to the society before dealing with them in any other way. Not for the first time the practitioner is urged to secure X-ray examination in all cases of injury which may have caused fracture or dislocation or to provide proof that X-ray examination was advised but refused. He should also be as careful as it may be to keep accurate records of all work done for individual patients at the time when treatment is carried out. This advice applies even to dental practitioners who see a great patient of whom they have no knowledge. A defence society can be seriously embarrassed in the task of defending a dental member through want of accurate entries in his dental charts. Many a panel doctor would have been saved anxiety if he had made systematic entries on his record cards, especially entries of visits to patients. It is not mental anxiety alone that the incalculable risks of litigation inflict. Financial loss is also involved.

Reports of a defence society's operations, describing legal action taken to check or defeat some claim against a professional man frequently have occasion to record that the claimant was a person without means and that it was useless to attempt to recover the costs. When a society takes up a case, it pays all the costs of its member whether he be plaintiff or defendant and whether he succeeds or not. If the society recovers damages for a member he receives them without deduction. Societies can offer these advantages because members' subscriptions make them possible. The bigger the membership the greater its resources for mutual protection.

ALLERGY AND NEPHRITIS

REFERENCE was made in these columns a year ago¹ to the experimental production of a glomerulonephritis histologically similar to Bright's disease in man by the injection of heteronephrotoxins. This work, originally brought into prominence by Matsugi, was confirmed in Edinburgh by Arnott Kellar and Matthew using rabbits. The method they adopted in brief was to subject rabbits to a series of intravenous injections of duck's serum the ducks having previously received numerous intraperitoneal injections of a suspension of rabbit kidneys. The rabbits so treated showed a glomerulonephritis closely comparable to human Bright's disease. The experimental facts may now be taken as established but the mechanism of causation remains doubtful. Most observers seem to agree that the nephritis is an allergic manifestation but this statement leaves us in some doubt as to what actually takes place in the body. Amongst points awaiting clarification are the following. First we need to know whether the nephrotoxin is specific for the kidney or whether comparable effects can be produced by sera prepared from other organs. Klinge and Knepper consider that it is only one of several factors required to induce sensitisation and is not specific. Next it has been suggested that the effect on the kidney is due to a haemolysin evoked by blood included during the preparation of the serum. But Arnott Kellar and Matthew perfused the kidneys of their rabbits with saline to remove blood, if therefore appears that a haemolysin can be excluded in their experimental nephritis. Other workers however state that when perfused organs are used a tubular degeneration only is induced by the prepared serum. Lastly it is claimed by Knepper that the so-called localisation of allergic response can be observed after the use of mechanical, thermal, pharmacological, and hormonal factors.

A theory deserving close attention is that advanced by C. E. Kellitt² who suggests that the mechanism involved in this experimental nephritis is that of reversed anaphylaxis. By this as he has explained in an earlier paper³ it is understood that the anaphylactic reaction ensues when circulating antibody unites with antigen which is fixed to the cell—in contrast to the usual type of reaction in which the antibody is fixed to the cell and the antigen is in the circulation. Kellitt thinks that the procedure involved in the experimental nephritis under consideration closely mimics the mechanism of reversed anaphylaxis. Glomerulonephritis in man he suggests may result from a reaction between antibodies elaborated by the body in response to an infection and the toxins resulting from that infection which have become fixed to the tissues more particularly

¹ *Lancet* 1936 1 118.

² *Ibid.* 1936 2 1272.

³ *J. Path. & Bact.* 1935 41 19.

the kidney which is concerned in their elimination. While this hypothesis is as yet unsubstantiated it is of interest that Kellett finds² a sharp fall in the complement in a small series of cases of acute Bright's disease, suggesting that an extensive antigen antibody reaction has taken place. No comparable fall was found in a control series, including cases of chronic nephritis. The whole subject of experimental nephritis and so called "nephropathy" has recently been ably reviewed by H. Horn.⁴ His comment upon the production of nephritis by parenteral injections of proteins and nephrotoxins is as follows—

"Repeated parenteral injections of protein have been shown to produce marked glomerular and tubular changes and occasionally to result in the reactivation of the mesenchymal elements of the interstitial tissue. The results with isonephrotoxins and autonephrotoxins have been inconclusive. With heteronephrotoxins on the other hand, marked abnormalities of the renal structural units have been obtained, their distribution and intensity varying with the dose of the injected material. The significance, however, of the hemolytic factor which seems to be common to all serums employed in these experiments has not been definitely shown. In spite of this, the pictures described indicate that the presence of a state of hypersensitivity is largely responsible for the appearance of the more widespread changes and seems to substantiate further the contention that tissue allergy is essential for the production of a diffuse non suppurative renal lesion."

CHEMOTHERAPY OF STREPTOCOCCAL INFECTIONS

EVERY week now sees fresh developments in the chemotherapy of streptococcal and other bacterial infections, and the situation is becoming increasingly complex in two distinct ways. In the first place, the supremacy of sulphanilamide, which is the active derivative of the original Prontosil and has superseded it in therapeutics, is now being challenged by other related compounds, and on present information it seems scarcely possible to assess their relative merits even in streptococcal infections alone, while their wider potentialities at least in the clinical field, are almost completely unknown. Dr G. A. H. Buttle and his colleagues reported in our issue of June 5th some preliminary observations on two new compounds, diammosulphone and diminosulphone, the efficacy of which in relation to their toxicity is greater than that of sulphanilamide, at least in experimental infections in mice. Another compound, *p*-benzyl aminobenzenesulphonamide, marketed in this country under the name of Proseptasine, entered the therapeutic field some time ago with less experimental backing than that which has accumulated in connexion with sulphanilamide, and the results reported by Dr L. E. H. Whitby (*p* 1517) in this issue are accordingly welcome as confirmation of its experimentally demonstrable efficacy. The chief advantage of this compound is that it is decidedly less toxic than sulphanilamide, at least as measured by determining the maximum tolerated dose in animals. Favourable clinical reports on it have appeared in France. Bloch, Michel, Conte, and Durel,⁵ for instance, treated 180 cases of erysipelas with excellent results. Let it not be supposed, however, that these are the only compounds related to sulphanilamide with which experimental and clinical research will have shortly to deal for other reports are already appearing in which freshly synthesised compounds of this nature are mentioned as yielding promising initial results.

A greater variety of infections are also being treated. While the hemolytic streptococcus is still the outstanding organism of proven susceptibility, experimental evidence justifies the adoption of this treatment in meningococcal meningitis, although clinical reports on its effect are still scanty, and in mouse infections there has been experimental success with bacteria of the enteric group and with the pneumococcus. According to Branham and Rosenthal,⁶ the combined use of sulphanilamide and serum is more effective than either alone in pneumococcal and meningococcal infections in mice. We also noted last week a paper by Dees and Colston of Baltimore, describing a degree of success in the treatment of gonorrhoea with sulphanilamide that has evidently impressed and perhaps surprised these authors themselves. There are thus three genera of bacteria—streptococcus, bacterium, and neisseria—which include one or more species susceptible to the action of these drugs, and it is not unlikely that others will be included shortly.

The Council on Pharmacy and Chemistry of the American Medical Association has now published a report⁷ briefly setting forth the steps by which the present position has been reached and approving sulphanilamide "for inclusion in New and Non official Remedies as a therapeutic agent for the treatment of infections by hemolytic streptococci of Lancefield's serologic group A." This report also adopts "sulfanilamide" as the non proprietary name for *p*-aminobenzenesulphonamide, and deprecates the coming of a variety of proprietary names for it. The Council finally announces its intention to "proceed with determining the acceptability of the various brands that have been submitted." This is likely to be no small task, and if the scope of the inquiry comes to embrace other related compounds it will strain the resources of the greatest medical organisation of the world to their utmost. That there is no official organisation in this country capable of conducting such an inquiry on the scale which may shortly be necessary makes us dependent on the work of individual observers, but they can at all events claim a very large measure of success in advancing this research within the past year.

A COMFORTABLE CURE OF THE OPIUM HABIT

WHATEVER adjectives their exponents may have applied to the various methods of treating opium addiction, it is doubtful whether any but the leucithin diet method has been described as comfortable. Wen-Chao Ma and his colleagues,⁸ who treated a number of Chinese opium smokers in this way and applied to it this epithet, found that, even when the patients remained at home without restrictions, the majority lost their desire for the drug in the course of a few days. The method, being both simple and inexpensive, was clearly worthy of further trial, and such has now been accorded it at the Carmichael Hospital for Tropical Diseases at Calcutta by R. N. and G. S. Chopra.⁹ They treated in all 200 patients varying in age from twenty to seventy years, 80 in hospital and 120 in the out-patient department, 2 being opium smokers, 1 a morphine addict, and the remainder taking opium by the mouth. Before starting on the special diet a careful history was taken and each patient had a thorough physical

examination any septic or toxic foci found being dealt with during the period of observation following treatment. In order to reduce withdrawal symptoms to a minimum it was found best to give lecithin and glucose on the day before the opium was to be completely withdrawn. One pill containing 10 grains of lecithin (Ovo Lecithin, Merck) was given three times a day usually for the first five days and 25 c cm of 25 per cent. glucose was given intravenously each morning for the first three or four days, glucose then being continued by the mouth. The diet otherwise consisted of fluids only for the first two or three days, light solids rich in protein and lecithin being added later when these could be taken. Usually no treatment was required after a week but in patients were kept under observation in hospital for 10-20 days and later they were seen as out-patients for 1-3 months or longer while they were accustoming themselves to a drug-free existence. During the withdrawal period especially on the first day most of the addicts suffered more or less from pains in the body and limbs, nausea and vomiting, constipation or diarrhoea, cardiovascular and vasomotor disturbances, spermatorrhoea, insomnia or anorexia, which required symptomatic treatment, the severity of these symptoms depending largely on the mental condition. The younger addicts and those who had not acquired a high tolerance showed as might be expected the best results, and of the entire series 70 per cent were completely cured and a further 10 per cent were able to reduce their dosage by four-fifths. In only 2.5 per cent was there complete failure and only 2.5 per cent relapsed within six months of discharge. It was concluded that the lecithin and glucose considerably reduced the risk, intensity and duration of the withdrawal symptoms and the method appears suitable for mass treatment and one which can be tried in the addict's house if his faithful co-operation is ensured.

MAGNESIUM AND VASCULAR SPASM

EVIDENCE that spasm of the terminal arterioles is concerned in a number of human diseases—particularly in nephritis—has been accumulating steadily. If only the physician had at his disposal means of checking such spasm, it is evident that considerable therapeutic advances might become possible. In this connexion some experiments by Rubin and Rapoport¹ deserve attention. It is well known that ergotamine tartrate by causing intense vasoconstriction can produce gangrene of the rats' tail. Rubin and Rapoport found that this gangrene is preceded and accompanied by a rise in systolic blood pressure. This is almost certainly a manifestation of generalised vasoconstriction, and the rat treated with ergotamine is therefore a useful test animal for studying the effect of various factors on vascular spasm. The investigators having previously shown that the magnesium ion is capable of preventing the contraction of plain muscle both *in vivo* and *in vitro* decided to study its effect on ergotamine hypertension. A group of rats were accordingly fed on a diet containing 2 per cent of magnesium carbonate, a proportion too small to cause diarrhoea. After three weeks the blood pressures were measured and subcutaneous injections of ergotamine tartrate were given. The blood pressure remained within normal limits although control rats which received similar treatment but no magnesium developed gross hypertension. Magnesium did not however protect the

animal from gangrene of the tail. In further experiments it was found that animals protected by magnesium developed hypertension when the latter was withdrawn, and conversely that established hypertension in control rats could be corrected by adding magnesium to the diet. It seems fairly certain that magnesium exerts its effect by relaxing the peripheral vessels and the question arises whether the spasm of human disease is likely to respond to such simple measures. Magnesium salts have of course been used by physicians for centuries and it seems incredible that dramatic reductions of blood pressure of the order of those observed by Rubin and Rapoport could have been overlooked. On the other hand the human alimentary tract does not absorb magnesium very easily and it is possible that parenteral administration might be more useful.

MR J G KETCHEN

THE Hospital for Sick Children, Great Ormond-street, has lost a good friend by the death on May 15th of John Gavin Ketchen in his eightieth year. In early life he was representative in London of several important provincial newspapers and knew many of the great Victorian statesmen and men of letters. He was fond of travel and became a fellow of the Royal Geographical Society. But in later years it was in the philanthropic world that he was best known for his sympathetic personality and his courtesy made him a formidable beggar for good causes and he was responsible for collecting the large sum of £500,000 for the Earl Roberts Memorial with which he was associated. In 1923 he became financial secretary at Great Ormond-street and shortly after his appointment he was able to obtain the support of the Prudential Assurance Company for a research department lately instituted there. He also interested the late Mr Bernhard Baron and the late Sir Basil Zaharoff in the work of the hospital and it benefited much thereby. In his appeal work he was greatly helped for many years by his daughter; but he was well aware of the importance of a personal approach and he would often work until midnight writing letters with his own hand which rarely failed to persuade his correspondents that it is more blessed to give than to receive. Late in life he became a Freemason and achieved the rare—perhaps unique—distinction of becoming Master of his mother lodge at the advanced age of 78.

On Thursday July 8th at 3 P.M. Queen Mary will open the new medical block of St Bartholomew's Hospital. It is to be called the King George V building.

THE third annual exhibition of the Medical Art Society will be held at the Royal Society of Medicine during the first fortnight in July. It will be open at noon each day (except Saturday) from Thursday July 1st to Wednesday July 14th. Admission is free without ticket.

THE out-patient arrangements committee of King Edward's Hospital Fund for London have this week issued a memorandum on Time-saving Methods in connexion with Arrival and Registration of Out-patients. The committee, over whom Dr H. Morley Fletcher presides, say that much has been done to shorten the interval between the patient's arrival and his interview with the doctor, but they have many suggestions to offer for further improvement. The report may be had from Geo. Barber and Son Ltd, Farnival-street F.C.4 at 11d. post free.

SPECIAL ARTICLES

THE ORGANISATION OF A VOLUNTARY HOSPITAL BLOOD TRANSFUSION SERVICE *

B1 S C DYKE, D.M., F.R.C.P.

PATHOLOGIST AND DIRECTOR OF THE BLOOD TRANSFUSION
SERVICE THE ROYAL HOSPITAL, WOLVERHAMPTON

A READILY available supply of blood for the purposes of transfusion is a necessity for every hospital of any size. Beyond the technical difficulties of withdrawing and storing it in a sterile state there appears to be nothing against the establishment of depôts of bottled or canned blood, but to solve these difficulties will involve considerable labour and expense and until they are solved hospitals must depend upon blood brought to them by donors on the hoof. Thus demands a corps of readily available donors and the means of getting them when required to the hospital in the shortest possible time.

In London the requirements of the hospitals are met by the London Blood Transfusion Service. In some large towns the British Red Cross has taken on the organisation of blood transfusion services. In most places the establishment and maintenance of the hospital blood transfusion service will fall upon that officer of the hospital who feels it incumbent upon himself to undertake it.

Experience in the organisation of the transfusion service of the Royal Hospital, Wolverhampton, may prove useful to those who are struggling with the same problem elsewhere and is therefore here recorded.

The service was first organised some ten years ago, a plea was made through the press for donors and met with a good response. As a result a roster of about 50 was established. All donors not only gave their services free but also arranged for their own transport to and from the hospital. Most of them were working men, and often the giving of their services entailed to them pecuniary loss not only in the cost of transport but also in time lost from work. For the most part these donors responded readily when called upon, and on no occasion was any complaint of time and money lost or any demand for remuneration received. The hospital is deeply indebted to them.

The service was run from the pathological department of the hospital and as transfusions increased in frequency became an ever increasing addition to the work of an already fully occupied department. Difficulties involving the expenditure of much time and energy were perpetually arising in getting hold of donors, and, particularly at night, in arranging transport. It became evident that the organisation and maintenance of the service could no longer depend entirely upon the staff of the pathological department.

On the suggestion of the house governor, Mr W. H. Harper, the needs and difficulties of the hospital in this respect were laid before the then president of the Rotary Club, Mr J. Whitehead. To him the state of affairs immediately presented itself as an opportunity for putting into effect the club motto "Service for All." He called a meeting of the Rotary Club at which the director of the service was given an opportunity of explaining what was

required, the appeal met with a gratifying enthusiastic reception. A similar address was given to the affiliated Round Table Club and as a result the two clubs undertook to organise not only a donor but also a transport service.

The organisation of the combined service was delegated to Rotarian E. G. Matthewman and Tabler L. R. Guy, both of Wolverhampton. The result of their efforts has been to place at the disposal of the Royal Hospital a blood transfusion service, with associated transport service, which have since worked and continue to work with the utmost efficiency and—so far as its hospital end is concerned—with amazingly little effort.

TRANSFUSION OFFICER

In order to secure so far as possible the efficient working of the service on the hospital side and in particular with a view to ensuring that withdrawals

FORM 1

ENROLMENT FORM—BLOOD DONOR

I freely offer myself for Blood Transfusion, and undertake to be ready to proceed to The Royal Hospital when called upon.

DATE _____ SIGNED _____

Mr.
Mrs.
FULL NAME _____ Age _____

ADDRESS _____

If a member of any Social Service Organisation. Please give particulars _____

Days and times when it is convenient for me to have Group Test taken at The Royal Hospital as set out below —

Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday

of blood were made by someone thoroughly experienced in the procedure, the hospital established the post of blood transfusion officer, this is combined with that of resident assistant pathologist. The duties of this officer are defined as follows —

1 The transfusion officer shall work under the supervision of the director of the transfusion service.

2 He/she shall have charge of the files of donors and of transport and of all other documents in connexion with the service.

3 He/she shall deal with the enrolment of new donors and shall see that on enrolment their blood groups are ascertained the Wassermann reaction examined, and the results properly and punctually recorded.

4 He/she shall see that all solutions necessary for the performance of transfusions and all the apparatus required for the withdrawal of blood and in the performance of transfusions is available in the laboratory and in a condition for immediate use.

5 Unless either a member of the honorary staff or the resident assistant surgeon expresses his intention of doing so it shall be the duty of the officer to withdraw the blood from the donor.

* Contribution to discussion at the summer meeting of the Association of Clinical Pathologists Hastings June 12th 1937.

5. If called upon to do so the transfusion officer shall either himself perform the transfusion or shall assist a member of the honorary staff or the resident assistant surgeon in its performance

ORGANISATION

The smooth working of the organisation has largely depended upon the series of enrolment and record forms designed by its secretaries. The methods of business organisation are strange to most medical men and it may be worth describing these forms in case they may prove useful to others.

Form 1 is filled in in duplicate on enrolment by the donor and handed over to one of the secretaries. It gives times convenient to himself at which the volunteer can attend at the pathological department for examination of his blood. The original is forwarded to the house governor of the hospital who after consultation with the blood transfusion officer fills in Form 2 and sends it to the volunteer in question.

Form 3 is filled in when the volunteer arrives at the pathological department. The upper portion of this form gives details of the availability of the volunteer. The lower portion is devoted to medical details of his blood group and general suitability. On completion this form is forwarded to one of the

FORM 2

BLOOD TRANSFUSION SERVICE

Dear _____

The Board of Management of the Royal Hospital tender to you their grateful thanks for your kind offer to become a member of the Blood Transfusion Service.

In order that the usual test may be taken will you kindly attend here on _____ the _____ at _____ Please ask for _____ who will take the test.

Yours very truly

DOCKE GOVERNOR & SECRETARY

To

secretaries by whom Form 3A is filled in. This is the final record and is a filing card. It is kept in four colours each of which indicates one of the four blood groups. The appropriately coloured and designated card is filled in according to the data supplied on Form 3. Besides reproducing the information given on

REMARKS.

This Form when completed to be forwarded with Enrolment Form and duplicate of House Governor's letter to one of the undersigned Joint Honorary Secretaries to enable the records to be completed.

1. ROTARIAN E. C. MATTHEWMAN, Bankers Bank, Ltd., 5, New St., Wolverhampton. Telephone 2202.
2. TABLER L. R. GUY, B. Birmingham, Ltd., 5, New St., Wolverhampton. Telephone 2422.

are provided with special labels fixable to the windscreen of the car, these bear in large letters the words "EMERGENCY CAR" and in smaller "The Royal Hospital Blood Transfusion Service". Each label issued also carries a registration number by which the identity of the person to whom it was issued may be known. Cars showing this label are given precedence over all other traffic.

The routine for the enrolment of the transport volunteers involves no medical work and is undertaken entirely by the secretaries. Final entry of the details is made on Form 8 which is again a filing card.

When completed, the filing cards—Form 3A for donors and Form 8 for transport volunteers—are returned to the pathological department where they are kept in a file under the charge of the director of the service.

When a donor is required, several cards of suitable donors are selected and handed into the telephone office of the hospital from which the call is sent out. If transport is required calls are similarly sent out to a transport volunteer living in the same district. A donor having been secured, the cards are returned to the transfusion officer by whom the requisite entries are made.

Form 5 is sent to the donor as a recognition of his services, it is the only recognition he gets.

SERVICE REGULATIONS

The following regulations govern the working of the service within the hospital—

1 Whenever time allows an attempt shall always be made to secure the services of friends or relatives of the patient as donors, before a call is made upon donors enrolled in the blood transfusion service of the hospital.

2 Whenever a donor under the service is called upon, arrangements shall be made for his reception immediately on arrival at the hospital, and for the withdrawal of blood and his release at the earliest possible moment.

FORM 5

THE ROYAL HOSPITAL, WOLVERHAMPTON

Blood Transfusion Service

IS HEREBY RECORDED THAT

voluntarily gave Blood for Transfusion at the Hospital on

to aid an unknown sufferer.

Service

Head Governor & Secretary

3 Except in cases of extreme urgency, a direct matching of the red cells of the proposed donor against the serum of the proposed recipient shall always be made in the pathological department under the supervision of the director of the transfusion service, or his deputy before a donor is actually selected for use.

4 Blood shall only be withdrawn with the donor in a recumbent position.

5 The withdrawal of blood shall be made either by a member of the honorary staff, the resident assistant surgeon, or the transfusion officer. Resident officers other than those named shall not withdraw blood from donors under the service.

6 Withdrawal of blood from donors under the service shall be made by means of venipuncture only, under no circumstances shall the vein be exposed. A local anesthetic shall always be used before needling the vein.

7 Donors shall remain recumbent for at least ten minutes after the withdrawal of blood. Thereafter they may be allowed to leave the hospital. Donors during their attendance at hospital must be treated with every possible courtesy and attention.

CONCLUSION

Since its inception two years ago the system has worked with the maximum of efficiency and the minimum of trouble, the shortest time to elapse between the sending out of a call for a donor and his appearance at the hospital has been two minutes and even at night the time has never exceeded two hours. All lay workers—secretaries and donor and transport volunteers alike—give their services without remuneration. Even the printing and stationery has through the kindness of a member of the Rotary Club been provided free of charge. The service is designed and maintained entirely for the benefit of the patients in the Royal Hospital. Neither donor nor recipient is

ever made aware of the identity of the other. The question of making the services of the volunteers available for patients outside the hospital has been freely canvassed. It was feared that this might lead to exploitation and it has not therefore been put into effect.

On behalf of my colleagues on the staff of the Royal Hospital I should like to take this opportunity of thanking publicly the organisers, the secretaries and all volunteers.

MEDICINE AND THE LAW

Doctors and Panel Dentistry

WHEN in 1921 the Dentists Act conferred a monopoly of dental practice upon registered dentists there was a saving clause to protect the practice of dentistry by a registered medical practitioner. This did not mean that the registered doctor when practising dentistry became for all purposes the equivalent of a registered dentist. The Dental Benefit Regulations for instance do not contemplate that a panel patient shall receive dental treatment from a doctor. The regulations declare that the patient may have dental treatment from any dentist who is prepared to provide such treatment at scale fees. The word "dentist" in this context means a registered dentist; the medical practitioner unless his name appears also on the Dentists Register is excluded.

The point was made clear last week in *Bynoe v. General Federation of Trade Unions Approved Society*. A man named Evans being a member of the defendant society received dental treatment from Dr. Bynoe who sent the society an account for £1 12s 6d on the prescribed form known as a dental letter. The approved society told Mr. Evans that it could not pay the account. Dr. Bynoe's name not being on the Dentists Register. The society suggested that Mr. Evans should get an estimate from somebody who was registered as a dentist. Dr. Bynoe then applied to the High Court for an injunction to prevent the defendant society from saying or writing that he was a person not entitled to give dental service or to receive payment for such service under the National Health Insurance Act. Clearly the society was in the right inasmuch as the wording of the regulations excluded dental service by anyone but a registered dentist. Dr. Bynoe as Mr. Justice Simonds observed was not a person with whom arrangements had been made to give dental treatment in accordance with the Dental Benefit Regulations. He could therefore not succeed unless he could impeach the regulations as *ultra vires* and void. The regulation making powers given by the National Health Insurance Act are wide: they not only cover many purposes where such powers are expressly conferred but they also extend to the elastically stated purpose of carrying the Act into effect generally. The court decided that there was no substance in the suggestion that the Dental Benefit Regulations or any of them were *ultra vires*. There may, said the judge, "be persons not on the Dentists Register who are quite competent to give dental treatment, but I can quite understand the Minister of Health confining the right to give dental treatment under the Act to those persons who are on the Dentists Register."

Synthetic Vinegar

The Food and Drugs (Adulteration) Act penalises the sale of substances not of the nature, substance and quality demanded by the purchaser but does not

attempt to prescribe specific standards for all conceivable foods and drugs. The magistrates, if there is no prescribed standard must listen to the evidence and adopt their own standard. They must decide for instance whether if a purchaser asks to be supplied with vinegar a synthetic substance can be served. The Westminster city council recently brought a test case on this point. A fish frier was fined £5 with 25 guineas costs for selling vinegar which, on analysis was found to consist of acetic acid and water coloured with burnt sugar. The council contended that vinegar means brewed vinegar and that brewed vinegar has a distinct and pleasant aroma which synthetic vinegar does not possess. If a purchaser asks for vinegar and is given synthetic vinegar he should be told what he is getting. On appeal to the London sessions the conviction was confirmed. There was evidence that

table vinegar is the trade name for synthetic vinegar, that the manufacturers have had no complaints and that 80 to 90 per cent. of the vinegar trade is in the non fermented or synthetic type. The appeal tribunal dismissing the appeal with 75 guineas costs expressed itself as satisfied that if sold without qualification the substance offered as vinegar or table vinegar was the product of fermentation. The court thus falls into line with the decision in *Preston v. Jackson* (1929) or perhaps carries the decision a little further. Synthetic vinegar plainly cannot be sold as malt vinegar: the recent case suggests that it cannot be sold as table vinegar either. There seems no reason why trade interests should find a way round the Food and Drugs (Adulteration) Act by inventing a commercial name which does not tell the purchaser what he may want to know.

These decisions grow more important as the commercial application of chemistry is developed. In *Bowler v. Woodroffe* (1928) a bottle bore the label "extract of meat and malt wine." The prosecution argued that the word "wine" implied the presence of the fermented juice of the grape. The analyst's certificate said Mr. Justice Avory stated that the article was not a meat and malt wine: the magistrate therefore unless any evidence qualified or contradicted that statement ought to hold that the article was sold to the prejudice of the purchaser. There are probably considerable opportunities for enforcing the law in respect of synthetic lime-juices, lemon squashes and fruit juice products. It would be interesting to see what evidence is given of the inferiority of the synthetic article in respect of taste, flavour or dietetic value.

NEW BUILDING FOR THE GENERAL NURSING COUNCIL. The new home of the council which is to be opened to-day, Friday by the Princess Royal, occupies the site of two houses built between 1776 and 1778 from the designs of Robert and James Adam. Although the paintings (attributed to Cipriani) on the ceilings were done on paper which was stuck to the plaster ceilings in the old houses, they were all successfully taken down unharmed and incorporated in the designs for the new ceilings after the necessary cleaning and repair. Some mahogany doors and fireplaces as well as the iron balustrading on the main stair landings and a beautiful fanlight over the front door were taken from the council's former offices at No. 20 Portland place. The outside of the building is faced with Portland stone and the stairs up to the second floor have margins of marble while the hall and stairways are panelled with marble. The council room is panelled with sycamore and other woods used for rosmos on the first floor are cherry, Indian laurel, English walnut and Honduras cedar. The new address of the council is 23 Portland place, W.

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations. Each contributor is responsible for the section for a month, his name can be seen later in the half yearly index

FROM TWELFTH MAN

IV

It is difficult, and perhaps impossible, to eliminate entirely one's personal bias from a discussion of public questions. If I were asked my opinion of the National Campaign for Physical Fitness I should say that I saw no reason to believe that physical fitness and good health were synonymous terms, that brains and character were more important than physical fitness, that it was stupid to be more physically fit than was necessary for the daily performance of one's job and the enjoyment of one's recreation, that an inquiry into the mental health of the community and a campaign for mental fitness were of vastly more importance, that if our leaders were thinking of the next war, it would be wise to pay more attention to our intelligence quotients and less to our chest measurements, that if the hearties who directed this National Campaign were looking for a slogan I should suggest, 'The Lord taketh no delight in the legs of a man.'

This is not a complete view of this question, but I should be prepared to defend it as more rational than the views of the ardent physical campaigners. It is not, however, free from personal bias. It owes something to the fact that in the gymnasium I was wont to reach the top of the ropes—perspiringly last, that in the days when I considered it my duty to take a morning run I arrived back for breakfast feeling slightly sick and spent the rest of the day in a mental twilight, and that a mediocrity at ball games was early accepted as part of my inadequate endowment.

If it is of such childish reminiscences, with a nice admixture of acquired prejudice, that the rational opinions of our maturity are composed it is not surprising that Freud has issued a modern version of Cromwell's injunction: "Gentlemen, I beg you to remember, in the name of the Censor, that you *must* be mistaken." It is a comforting reflection that Freud does not escape his own net.

* * *

We are invited, as doctors, to believe that we have some specific contribution to make to the question of war and peace. The Medical Peace Campaign (which is not, as might be imagined, an organisation devoted to the propagation of peace amongst doctors) suggests "that the profession as a whole should be urged constantly to debate the problems associated with war and its causation much as it debates the etiology and prevention of disease." My reply would be that this last subject is our business, but with the former we have, as a profession, no concern. Indeed the intrusion of amateurs like ourselves into this expert field may even make war more likely, and cannot engender peace.

Moreover, doctors have no common opinion on such matters. Why should they? Are the members of the Medical Peace Campaign to be expected to agree with the opinion of Sir Arthur Keith 'that the world, we are afraid, must sleep forever with a loaded gun by its side'? I detest and deplore this attitude of Keith's, but his opinion and my dislike of it find no support in our professional knowledge.

Is democracy worth fighting for? Is the British Empire worth fighting for? Is the maintenance of a democratic state in Czechoslovakia worth fighting for? Was the independence of Abyssinia worth fighting for? We all, I hope, have our minds made up on these problems, as men, these questions touch us nearly, but as doctors not at all. We are urged by the Medical Peace Campaign to join the peace councils and the branches of the League of Nations Union. Why? And which? For all these different organisations have different opinions on this question of peace, and all of them give different answers to the four questions posed above.

But I shall be told that it is not suggested that medical opinion can have anything to do with immediate problems. It is the more remote and the more profound causes of war that are to be debated, considered, assessed, and eradicated, that the more important causes of war are psychological, and it is therefore the psychologist's business to explain and eradicate these causes not only in ourselves but in the Japanese, the Argentines, and the Greeks.

Well it may be so. And if it is so, it is a job not for the average doctor, not for the Medical Peace Campaign, but for the expert psychologist—and, saving their reverences, are any of them expert in this field? Trotter, who is genius enough to be expert in two worlds, wrote a magnificent book many years ago on "The Herd Instinct." His is still a lonely distinction. I have just read a pamphlet by Dr Burnett Rae, recommended by THE LANCET, entitled "Psychology and the Problem of War." It is sound and sensible but it contains no new ideas, and it could equally well have been written by an intelligent layman who was interested in the subject. I came with more hope to Graham Howe's new book, entitled "War Dance," and was the more disappointed. His book is full of good ideas but it is always difficult and often irritating. He has developed a highly stylised method of writing—Gertrude Stein married to James Joyce. Almost any page will show sentences of this sort, "The way of peace cannot be more sure than that of war accepted, peace about war, difference agreed upon, tolerant relations amidst the moving stress of opposing poles rhythm and harmony." Or this, "The unseen other aspect of this untimely error of masturbation is the Holy Spirit, source of communion, deepest ecstasy, but opposite pole. To interfere with one is to upset the other, to which the lower needs to be lovingly lifted." Ideas drowned in a sea of words. Such a book cannot be a practical contribution to the understanding of the causes of war.

* * *

Nothing makes me more warlike than the pronouncements of some psychologists on peace. I should have hesitated to make this admission if a distinguished psychologist had not told me that he was affected in the same way. It has become almost customary for a group of psychologists to issue round robins to the press at times of international crisis. It has seemed to me that these contributions exacerbate controversies without elucidating issues. To say that Germany since the Treaty of Versailles is suffering from an inferiority feeling is to say

what everybody knows diagnosis is easier therapy more difficult. To say that fear is the underlying cause of trouble in Europe, that Czechoslovakia is in an anxiety state is to announce a platitude. To declare in Rome that Mussolini's desire for empire springs from unpleasant psychological causes would be as heroic last gesture to say it in London is merely to cock an irritating snook.

To the rules I gave last week for the conduct of experts let me add one more for psychologists dogmatizing about international affairs. Psychotherapeutic technique which has not as yet been uniformly successful in individual disorders should be used sparingly in international affairs—and when used it should be limited in its application to the psychotherapist's own countrymen.

* * *

It is commonly held that science is an intellectual force that works for peace. If this is true at all it is true in the same or greater degree of art of literature of education of religion of trade of easy transport. Nationalist temper runs so high to day that it is difficult even for men of goodwill to emulate the serene detachment of Sir Thomas Browne when he wrote some hundred years ago in *Religio Medici*:

I feel not in myself these common antipathies that I can discover in others: those natural repugnances do not touch me nor do I behold with prejudice the French Italian Spaniard or Dutch but where I find their actions in balance with my countrymen I honour love and embrace them in the same degree.

* * *

If the propaganda in favour of euthanasia does nothing else it should develop a more balanced attitude towards the problem of suicide. It is difficult to understand the attitude of the Law and the Church: it almost certainly does not represent the mind of lawyers and churchmen. Most family doctors have witnessed a drama where suicide seemed the sane and obvious solution. The coroner occasionally receives a letter in which the writer states in restrained and dignified language that he has not wished to prolong an intolerable existence. A merciful but illogical jury brings in a verdict of suicide while of unsound mind because it is in England not only a disgrace but a crime that a sane man should die by his own hand.

The Romans viewed the question differently. Lecky in his *History of European Morals* quotes this noble passage from Seneca, "I will not relinquish old age if it leaves my better part intact. But if it begins to shake my mind, if it destroys my faculties one by one if it leaves me not life but breath I will depart from the putrid or tottering edifice. I will not escape by death from disease so long as it may be healed and leaves my mind unimpaired. I will not raise my hand against myself on account of pain for so to die is to be conquered. But if I know that I must suffer without hope of relief I will depart not through fear of pain itself but because it prevents all for which I would live."

* * *

Raymond Asquith was in a company where this problem was being debated and he was maintaining that suicide was often justifiable but it should be encompassed in as tidy and as dignified a manner as possible and that all the great historical characters who had died by their own hands had thus improved the occasion. What about Judas Iscariot? asked someone irrelevantly. Oh that's the worst of these nouveau riches said Raymond Asquith.

Sir William Willeox and his friends may be said to have won the Battle of the Barbiturates. The family physician views this victory without enthusiasm and even with distaste. The result for him is a few more regulations to be observed. In a town of 150,000 people in which I write, some hundreds of thousands of barbiturate tablets are consumed by the inhabitants every year. There has never been a case of barbiturate poisoning here and it was a safe bet that there would never be one. The family doctor knows that the barbiturates are not drugs of addiction and he sees himself condemned to observe tiresome regulations because a handful of neurotics in London chose to imitate one another in this method of committing or attempting to commit suicide. Before the issue of the new regulations this fashion was already abating. In the provinces the rope the knife the river and the gas oven are the methods of election. And these remain uncontrolled. The socially important reason for a Dangerous Drugs Act is not that such drugs when taken in excess, kill but simply that they create a craving and produce an appalling mental and moral disintegration. Nothing of the sort can be urged against the barbiturates.

* * *

As the years pass it becomes increasingly unlikely that any attempt will be made to control the patent medicine industry. The enormous advertising revenues which the trade brings to newspapers make it a hot subject for any Government to handle. Is it too much to hope however that we may get some thing done about the proprietary preparations of reputable manufacturing druggists? Many of the manufacturing houses have put advancing medicine heavily in their debt. Progress and profit have gone hand in hand. A few of them have been from a scientific point of view almost without blemish. But even the best of them are sometimes guilty of the higher charlatanism and their besetting sin is still as it was thirty or forty years ago polypharmacy. A very distinguished American firm is at the moment pushing a preparation containing liver stomach concentrate iron and vitamin B. This is blunder bus prescribing of the worst sort. These are substances which have in modern therapeutics a well-defined and limited value. To say this is not to ignore the facts that there is a small minority of patients with pernicious anaemia who benefit by iron therapy and that a handful of patients with microcytic anaemia improve more rapidly with liver extract added to iron. To suggest that this product should be used in all anaemias where the facilities for making a definite diagnosis are temporarily not available is to invite the doctor to share in a make believe. To suggest further that this product may be of value in clinical conditions without anaemia characterised by loss of appetite weakness fatigability or under-nutrition is to descend to the level of the advertisement of patent medicines.

I have before me a list of the proprietary preparations used by one of the most renowned manufacturing chemists in the world. The list contains more than 200 products some of the highest value; but at least 10 per cent of them could not be supported by any scientific justification. Two brands of liver extract have recently been advertised. One was described as the purest available and the other as

from twice to forty times as pure as any other liver extract. Lord Baldwin likes to refer to the many-sidedness of truth. The truth must not only be

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations. Each contributor is responsible for the section for a month, his name can be seen later in the half yearly index

FROM TWELFTH MAN

IV

IT is difficult, and perhaps impossible, to eliminate entirely one's personal bias from a discussion of public questions. If I were asked my opinion of the National Campaign for Physical Fitness I should say that I saw no reason to believe that physical fitness and good health were synonymous terms, that brains and character were more important than physical fitness, that it was stupid to be more physically fit than was necessary for the daily performance of one's job and the enjoyment of one's recreation, that an inquiry into the mental health of the community and a campaign for mental fitness were of vastly more importance, that if our leaders were thinking of the next war, it would be wise to pay more attention to our intelligence quotients and less to our chest measurements, that if the hearties who directed this National Campaign were looking for a slogan I should suggest, "The Lord taketh no delight in the legs of a man."

This is not a complete view of this question, but I should be prepared to defend it as more rational than the views of the ardent physical campaigners. It is not, however, free from personal bias. It owes something to the fact that in the gymnasium I was wont to reach the top of the ropes—perspiringly last, that in the days when I considered it my duty to take a morning run I arrived back for breakfast feeling slightly sick and spent the rest of the day in a mental twilight, and that a mediocrity at ball games was early accepted as part of my inadequate endowment.

If it is of such childish reminiscences, with a nice admixture of acquired prejudice, that the rational opinions of our maturity are composed it is not surprising that Freud has issued a modern version of Cromwell's injunction: "Gentlemen, I beg you to remember, in the name of the Censor, that you must be mistaken." It is a comforting reflection that Freud does not escape his own net.

* * *

We are invited, as doctors, to believe that we have some specific contribution to make to the question of war and peace. The Medical Peace Campaign (which is not, as might be imagined, an organisation devoted to the propagation of peace amongst doctors) suggests "that the profession as a whole should be urged constantly to debate the problems associated with war and its causation much as it debates the ætiology and prevention of disease." My reply would be that this last subject is our business but with the former we have as a profession, no concern. Indeed the intrusion of amateurs like ourselves into this expert field may even make war more likely and cannot engender peace.

Moreover, doctors have no common opinion on such matters. Why should they? Are the members of the Medical Peace Campaign to be expected to agree with the opinion of Sir Arthur Keith that the world, we are afraid, must sleep forever with a loaded gun by its side? I detest and deplore this attitude of Keith's, but his opinion and my dislike of it find no support in our professional knowledge.

Is democracy worth fighting for? Is the British Empire worth fighting for? Is the maintenance of a democratic state in Czechoslovakia worth fighting for? Was the independence of Abyssinia worth fighting for? We all, I hope, have our minds made up on these problems, as men, these questions touch us nearly, but as doctors not at all. We are urged by the Medical Peace Campaign to join the peace councils and the branches of the League of Nations Union. Why? And which? For all these different organisations have different opinions on this question of peace, and all of them give different answers to the four questions posed above.

But I shall be told that it is not suggested that medical opinion can have anything to do with immediate problems. It is the more remote and the more profound causes of war that are to be debated, considered, assessed, and eradicated, that the more important causes of war are psychological, and it is therefore the psychologist's business to explain and eradicate these causes not only in ourselves but in the Japanese, the Argentines, and the Greeks.

Well it may be so. And if it is so, it is a job not for the average doctor, not for the Medical Peace Campaign, but for the expert psychologist—and, saving their reverences, are any of them expert in this field? Trotter, who is genius enough to be expert in two worlds, wrote a magnificent book many years ago on "The Herd Instinct." His is still a lonely distinction. I have just read a pamphlet by Dr. Burnett Rae, recommended by THE LANCET, entitled "Psychology and the Problem of War." It is sound and sensible but it contains no new ideas, and it could equally well have been written by an intelligent layman who was interested in the subject. I came with more hope to Graham Howe's new book entitled "War Dance," and was the more disappointed. His book is full of good ideas but it is always difficult and often irritating. He has developed a highly stylised method of writing—Gertrude Stein married to James Joyce. Almost any page will show sentences of this sort, "The way of peace cannot be more sure than that of war accepted, peace about war, difference agreed upon tolerant relations amidst the moving stress of opposing poles rhythm and harmony." Or this, "The unseen other aspect of this untimely error of masturbation is the Holy Spirit, source of communion, deepest ecstasy, but opposite pole. To interfere with one is to up it the other to which the lower needs to be lovingly lifted." Ideas drowned in a sea of words. Such a book cannot be a practical contribution to the understanding of the causes of war.

* * *

Nothing makes me more warlike than the pronouncements of some psychologists on peace. I should have hesitated to make this admission if a distinguished psychologist had not told me that he was affected in the same way. It has become almost customary for a group of psychologists to issue "round robins" to the press at times of international crisis. It has seemed to me that these contributions exacerbate controversies without elucidating them. To say that Germany since the Treaty of Versailles is suffering from an inferiority feeling is to say

what everybody knows diagnosis is easy therapy more difficult To say that fear is the underlying cause of trouble in Europe that Czechoslovakia is in an anxiety state is to announce a platitude To declare in Rome that Mussolini's desire for empire springs from unpleasant psychological causes would be an heroic last gesture to say it in London is merely to cock an irritating snook

To the rules I gave last week for the conduct of experts let me add one more for psychologists dogmatizing about international affairs Psychotherapeutic technique which has not as yet been uniformly successful in individual disorders should be used sparingly in international affairs—and when used it should be limited in its application to the psychotherapist's own countrymen.

* * *

It is commonly held that science is an intellectual force that works for peace If this is true at all, it is true in the same or greater degree of art, of literature of education of religion of trade of easy transport Nationalist temper runs so high to-day that it is difficult even for men of goodwill to emulate the serene detachment of Sir Thomas Browne when he wrote some hundred years ago in *Religio Medici* :

I feel not in myself those common antipathies that I can discover in others : those natural repugnances do not touch me nor do I behold with prejudice the French Italian Spaniard or Dutch but where I find their actions in balance with my countrymen I honour love and embrace them in the same degree

* * *

If the propaganda in favour of euthanasia does nothing else it should develop a more civilized attitude towards the problem of suicide. It is difficult to understand the attitude of the Law and the Church ; at almost certainly does not represent the mind of lawyers and churchmen. Most family doctors have witnessed a drama where suicide seemed the sane and obvious solution The coroner occasionally receives a letter in which the writer states in restrained and dignified language that he has not wished to prolong an intolerable existence A merciful but illogical jury brings in a verdict of suicide while of unsound mind because it is in England not only a disgrace but a crime that a sane man should die by his own hand

The Romans viewed the question differently. Livy in his *History of European Morals* quotes this noble passage from Seneca : I will not relinquish old age if it leaves my better part intact But if it begins to shake my mind if it destroys my faculties one by one if it leaves me not life but breath I will depart from the putrid or tottering edifice I will not escape by death from disease so long as it may be healed and leaves my mind unimpaired I will not raise my hand against myself on account of pain for so to die is to be conquered. But if I know that I must suffer without hope of relief I will depart not through fear of pain itself but because it prevents all for which I would live

* * *

Raymond Asquith was in a company where this problem was being debated and he was maintaining that suicide was often justifiable but it should be encompassed in as tidy and as dignified a manner as possible and that all the great historical characters who had died by their own hands had thus improved the occasion What about Judas Iscariot ? asked someone irrelevantly Oh that's the worst of these nouveaux riches said Raymond Asquith.

Sir William Willecox and his friends may be said to have won the Battle of the Barbiturates The family physician views this victory without enthusiasm and even with distaste The result for him is a few more regulations to be observed In a town of 150 000 people in which I write, some hundreds of thousands of barbiturate tablets are consumed by the inhabitants every year There has never been a case of barbiturate poisoning here and it was a safe bet that there would never be one The family doctor knows that the barbiturates are not drugs of addiction and he sees himself condemned to observe tiresome regulations because a handful of neurotics in London chose to imitate one another in this method of committing or attempting to commit suicide Before the issue of the new regulations this fashion was already abating In the provinces the rope the knife the river and the gas oven are the methods of election And these remain uncontrolled The socially important reason for a Dangerous Drugs Act is not that such drugs when taken in excess kill but simply that they create a craving and produce an appalling mental and moral disintegration Nothing of the sort can be urged against the barbiturates

* * *

As the years pass it becomes increasingly unlikely that any attempt will be made to control the patent medicine industry The enormous advertising revenues which the trade brings to newspapers make it a hot subject for any Government to handle Is it too much to hope however that we may get some thing done about the proprietary preparations of reputable manufacturing druggists ? CORRESPONDENCE

THE REVISED MEDICAL CURRICULUM

To the Editor of THE LANCET

SIR,—The recent session of the General Medical Council was largely occupied with consideration of the revised medical curriculum which the Council proposes should come into operation in November, 1938. Its resolutions show a general agreement with the recommendations for the reform of the medical curriculum contained in the report (April, 1935) of a conference of those licensing bodies whose qualifications are taken by students in the London medical schools. Upon this conference were representatives from the University of London, the Universities of Oxford and Cambridge, from the Conjoint Board of the Royal College of Physicians and the Royal College of Surgeons, and the Society of Apothecaries, but no representative of the General Medical Council. The recommendations of the conference concern only the London medical schools, but the resolutions of the General Medical Council as the statutory authority on medical education are operative throughout the United Kingdom and the Irish Free State.

Reform of the medical curriculum has been pressed from various sources for many years, and notably from the student body, of which the medical society of St Mary's Hospital was the first in the field in May, 1932, with a resolution "That the present system of medical education does not produce an efficient practitioner." In June, 1933, the students' union of Edinburgh University carried the campaign farther. At a discussion opened by the senior physician of Edinburgh Infirmary the following resolution was passed, with only seven dissentients in a large assembly:—

That this House places on record its opinion that the present system of medical education in this country is unsatisfactory. In its opinion important changes in the curriculum are essential, whereby more facilities for instruction in practical medicine are available and more assistance given in the principles and practices of preventive medicine. The time required for this additional teaching can, in its opinion, be obtained by a judicious modification of the teaching in the earlier scientific subjects, with some revision of the time and attention devoted to the teaching in the "specials" department of medicine and surgery.

This resolution expressed a very general opinion held by teachers, examiners, and the great bulk of the

(Continued from previous page)

many-sided but double-faced if it embraces such statements as these:

They do these things better in America. The American Association has had, for many years, a Council on Pharmacy and Chemistry which examines carefully and reports on "New and Unofficial Remedies" and the claims made for them. If the remedies are rejected reasons are given and many manufacturers find it worth while to make alterations in their products in the light of the council's criticism. If the remedy is rejected advertising space in the *Journal of the American Medical Association* is automatically refused to it.

Doctors are urgently in need of protection from this ever increasing spate of new preparations. Could not the journals, the reputable manufacturing houses, and a central pharmaceutical council coöperate after the American example?

How long, O Lord, how long?

members of the medical profession, as well as by the students who recorded it, and who are the persons most directly concerned. How far does the new official curriculum now propounded by the General Medical Council meet the need thus revealed?

It is clear from examination of the resolutions that the duration of study is to be materially prolonged. At present the regulations of the University of London and of the licensing corporations in London allow of completion of the professional education of the student $5\frac{1}{2}$ years after taking the matriculation examination in the case of London University, 5 years after taking that examination or its equivalent in the case of the licensing corporations. The matriculation examination or its equivalent can be taken at the age of 16. But the new regulations envisage 18 as the earliest age at which the medical student can begin his professional education thus adding two years to the pre-registration period. This provision is necessary to meet the new requirement that the student shall complete his education in the preliminary scientific subjects—chemistry, physics and biology—before coming to the medical school. The period of professional study—that is, between the date of passing this entrance examination and the date of the final qualifying examination—is made up of two phases, two academic years (nine months each) are to be spent in the study of human anatomy and human physiology, and for the first time the elements of normal psychology are to be added to this course, as well as instruction in the elementary methods of clinical examination including physical signs, the use of the stethoscope, ophthalmoscope, &c [sic], and some initiation into the principles of general pathology, bacteriology, and pharmacology. Eighteen months is likely to be insufficient to cover this greatly enlarged and highly heterogeneous programme.

The second phase, the period of clinical studies, is to occupy three calendar years (12 months each), during which "clinical instruction should be continuous." The effect of this unobtrusive transformation of academic into calendar years is to add nine months to the curriculum and contradicts the assertion contained in the earlier part of the official statement that the period of professional study may be completed in five academic years (the italics are mine). The provision of the extra nine months is rendered eminently necessary by the further expansion of the requirements in the clinical period, which now entail in addition to several new subjects cited below in which instruction is required, residence for four months during the clinical period in a hospital in order to follow more closely the practice of the hospital in medicine, surgery, and midwifery, to meet a very vocal public demand for better midwifery instruction, two of these four months are to be spent in a maternity hospital or the maternity ward of a general hospital and "these two months should be devoted exclusively to instruction in midwifery and in the hygiene of infants."

The call for training in preventive medicine is met by the following direction: "Throughout the whole period of study the attention of the student should be directed by his teachers (a) to the importance of the measures by which normal health may be assessed and maintained, and (b) to the principles and practice for the prevention of disease." This resolution bears an unhappy resemblance to the resolution adopted by the Council in 1922 which runs as follows:

Throughout the whole period of study the attention of the student should be directed by his teachers to the importance of the preventive aspects of medicine and it is safe to predict that the new resolution equally nebulous, will be ignored as completely as was its predecessor.

Preventive medicine thus does not get any precise niche in the new temple of learning but the following items are specifically added to the special subjects of the old curriculum: dietetics, therapeutics and prescribing physiotherapy principles of nursing child welfare, psychology radiology as applied to medicine and to surgery, disease in infancy and in childhood, dental diseases and instruction on the statutory obligations of registered medical practitioners.

The revision of the medical curriculum has been conducted by bodies in which the general practitioner has either not been represented at all as in the case of the conference or by a small minority as in the case of the General Medical Council. The passing of the National Health Insurance Act established the general practitioner once and for all as the most important unit in the medical service of this country inasmuch as the service given by the Act was expressly defined as a general practitioner service. By the operation of the same Act as Sir Kaye Le Fleming pertinently points out, a standard is afforded of the range of a general practitioner's duties; that standard does not envisage any specialist experience. The production of an efficient general practitioner should therefore be the principal aim of medical education. There is abundant and accumulating evidence that the curriculum has been overloaded in the past and a further addition to it is surely disastrous. An admirable presentation of the ideal curriculum was given by Prof. T. G. Moorhead when president of the Royal Academy of Medicine in Ireland.

During the first two years the preliminary sciences should be taught. He felt strongly that a sound knowledge of these preliminary sciences including biology was absolutely essential. In teaching the principles of these sciences facts bearing on the future life work of the student should be used as much as possible in illustration. In the second or clinical part of the course he felt that there was only time to give a man a thorough knowledge of the principles of medicine surgery and midwifery. Once these principles were acquired and once a student was placed in a responsible position himself he could acquire additional facts with extraordinary rapidity. If however as a student he was swamped in detail and failed to acquire a scientific outlook he could never hope in after life to be a really sound practitioner. As far as possible he should be made familiar with the everyday emergencies included in the so-called specialities but a systematic course should be reserved for post-graduate teaching.

Can the present position be viewed with anything but anxiety by those who are convinced that the minimal curriculum for qualification should be designed first of all to meet the needs of the general practitioner and that the effort to produce a general specialist which in itself is a contradiction in terms should be finally abandoned?

The expense of medical education both to the individual and to the State is creating a very difficult position. The medical profession is becoming practically closed except to those who have abundant financial means. The expenditure by the State in subsidising medical education is a growing burden upon the community and those responsible for its distribution are ever more insistently asking the question whether that expenditure is justified. Could there be a less opportune occasion for producing a

curriculum which must inevitably exact an increased expenditure both of time and of money?

I am Sir yours faithfully

E. GRAHAM LITTLE.

House of Commons June 17th

THE OVER TREATMENT OF GONORRHOEA

To the Editor of THE LANCET

SIR,—This correspondence began with a piffing complaint about the over treatment of a case of gonorrhoea in a V.D. clinic—piffing because a clinic medical officer in his dark and uncritical world, is rightly concerned rather about the under treatment of gonorrhoea—and was continued by the report of another over treated patient who harboured prostatic calculi. Before the calculi were so creditably discovered in other hands the clinic had apparently in this case too cured the gonorrhoea. Interesting and again piffing. And now Mr. Johnston Abraham hots it up with the story of a V.D. clinic's failure to recognise early a cancer of the bladder. From his account the clinic's treatment of the stricture made easy that cystoscopy in other hands which disclosed the cancer. Gratitude is hard to find! Moreover he forgetting as do the other two Superior Complainants, that most of us live and practise long enough to have the painful pleasure of correcting and being corrected by each other lets loose against his brethren (I dare not write colleagues) of the V.D. clinics our so-called venereal experts his distinguished and discourteous diatribe. Distinction was to be expected of him discourtesy not. (Venereal experts reminds me of the happy occasion at our hospital when an eminent physician whose friendship I have long valued and enjoyed presented me to a noted and now startled lady visitor as our venereal doctor.)

Mr. Abraham's misfounded unguarded charges against us of ignorant incompetence unenlivened even by the hope of one day sitting down with Olympians, need not be met. But you may take it, Sir, that the V.D. clinics are well lighted enough to uncover (but of course rarely) the blunders of others even of those in the illumined Soranian world (so Mr. Abraham would have it) of Genito Urinary Surgery.

May I not also report? I select from the last few years

A surgeon to the G.U. dept. of a hospital sent his patient who confessed to a gonorrhoea one year previously for treatment to the V.D. clinic; and found time to write the short report—"hematuria, staphylococci." The man engine-room greaser chose the clinic nearest his home—mine. I found staphylococci alright; but no hematuria and no g.c.; until a week later after the patient had gone motor-cycling both of us (he first) found hematuria all right and staphylococci and no g.c. And so soon to the stone in his kidney. I claim no credit that should go to the motor bike.

A senior retired ship's officer asked me in the V.D. clinic if he were fit to marry. He handed me medical reports from which could be learnt that in the G.U. dept. of a hospital four years previously he had had a testis removed for sarcoma. Later a pathologist reported gumma. Later blood-serum Wassermann positive. Later malnourished but untreated transferred to care of a physician (in whom it would be reasonable to look for that "widest possible knowledge of internal medicine") who prescribed a mixture to be taken for three consecutive months in every year and this the patient had done. The mixture was pot lod and living perilous. All made very easy for me. As for him there was now added into him Angell Robert on pupils and Wassermann positive cerebro-spinal fluid.

And now I should humble me

A steward was sent by his ship's surgeon to my clinic for "pus in urine ? g.c." I could detect no g.c., but did try to treat the painless bloodless "cystitis." After five weeks of it he vanished. Six months later back from a voyage he called at hospital to see me. Another steward had advised him, from first-hand experience, to try a "better clinic with younger doctors." So he did, and a young gentleman had "popped it into him good and quick," and he, the patient, heard the chink as "it" hit the stone. Operation had removed stone from bladder and symptoms with it. Nevertheless, he gave me to understand I had been the honourable trier that young fellow "seemed to chance it like." Justice is indeed hard to find!

In conclusion, Sir, may I remind Mr Johnston Abraham that from what he thinks of and despises as too stony a ground—"the mental outlook of the old dead and gone regimental medical officer"—was raised up besides John Hunter, a Helmholtz, a Laveran, a Bruce, Ross, and Leishman, and one who should surely be a father for this Abraham, a Peter Freyer. Doubtless he shares with me the privilege of having once known and sat under the last four and he has forgotten them. These ghosts will not trouble him even though grace is, for the moment, hard to find in him.

And I have the idea that some surgeons had for long a clear field and few rivals with gonorrhœa in the male—and left it to us "unsurgical" newcomers in the new V.D. clinics.

I am, Sir, yours faithfully,

H. M. HANSCHELL,

Hon. Med. Supt. and M.O. 1/c V.D. Clinic,
Royal Albert Dock Hospital, E.

June 20th

To the Editor of THE LANCET

SIR,—Mr Johnston Abraham's attainments and experience in the fields of urology and of the venereal diseases are so well known that his pronouncements must receive the greatest respect and attention. For this very reason I ask leave to join issue with him on the subject of his recent damaging statements as to the training and standard of work of the venereal specialist.

Few will deny that there are disadvantages in the present system, and I believe that most medical officers of venereal diseases clinics would admit that the treatment of some patients with gonorrhœa is continued beyond the stage in which the benefit of treatment is apparent. The reason is to be found, not in the ignorance and carelessness of the medical officer, as Mr Abraham suggests, but in the realisation that, in the light of modern improved pathological tests, such patients cannot be regarded as non-infectious. The medical officer is between the Scylla of releasing the infectious patient, and the Charybdis of prolonging treatment unduly. Since he is unwilling to admit, even to himself that in such patients the disease is in eradication, he chooses the second alternative.

Mr Abraham truly says that venereal disease has always been the Cinderella of medicine but I cannot agree that the remedy lies in restoring syphilis to general medicine and gonorrhœa to urology. It is to the past neglect and indifference of the physician and the urologist that the present 'lowly position' of the venereal diseases is due. I believe that most of the shortcomings of venereal diseases clinics arise from an attitude of mind which Mr Abraham's letter well exemplifies. The student gains the impression from his medical and surgical instructors that the subject of the venereal diseases is an unworthy and slightly unsavoury study which no competent man

in his right mind would adopt as his sole life's work. In consequence there is small incentive for a man with the necessary medical and surgical background to regard the venereal diseases department as other than a possible convenience—a stepping stone to higher things. The appallingly high incidence of these diseases among the general population has compelled the public health authorities to intervene and endeavour, by public organisation and subsidy, to provide a remedy for a situation for which the medical profession as a whole is woefully to blame. The present inadequacy of the treatment of gonorrhœa must be regarded as a direct legacy from the past neglect of the urologist.

Mr Abraham deplores with Mr Nicholls the "unhappy and incompatible" marriage of two such widely dissimilar diseases as gonorrhœa and syphilis, yet he himself has shown by his able writings on the subjects of the treatment of both these diseases that the gulf of dissimilarity can be bridged. To the venereal diseases medical officer this incompatibility is less obvious since his daily problems in psychology, arising from the patients' shame and the necessity for concealment, and his difficult task of handling family situations, are almost identical in relation to the two diseases. There is also the practical consideration that it is common to find patients who are suffering from both gonorrhœa and syphilis. There are manifest advantages in treating both infections in the same department.

A sound knowledge of the fundamental principles of medicine and surgery is essential in venereal diseases practice as in all other branches of medical science, but the occasional dabbler in surgery, the surgical tinker, is always a menace. I do not agree that it is either necessary or desirable for the venereal diseases officer to be able to perform the surgical operations which Mr Abraham enumerates. The necessity is a close liaison between venereal disease departments and the departments of gynaecology and urology. By this means a competent surgical opinion is always available, and the venereal diseases cease to "live apart in a dark and uncritical world of their own."

Mr Abraham describes one case in which the blunder of a venereal diseases officer resulted tragically for his patient. It would be possible to give other instances where ignorance of the fundamentals of the diagnosis and treatment of venereal diseases on the part of the urologist and physician have resulted most tragically for patients and their families. But such recriminations are valueless and even harmful. From the wealth of Mr Abraham's experience one might have hoped for some more helpful and constructive suggestions in dealing with the undeniable difficulties of the present situation.

I am, Sir, yours faithfully,

Harley street W. June 21st AMBROSE J. KING

RECENT ADVANCES IN OBSTETRICS

To the Editor of THE LANCET

SIR,—In the report of Miss Keren Parkes's paper at the London Association of the Medical Women's Federation published on p. 1465 of your last issue, there are two mis-statements which I feel should be corrected.

(1) Discussing the *Aschheim Zondek* and *Friedman* tests Miss Parkes is quoted as stating that these tests are of use in the diagnosis of intra uterine death of a foetus. I published a small series of cases in which the date of intra uterine death was known (*Lancet* 1935 2, 364). In two the Friedman test was still positive 6 weeks after the foetus died. In

the reports of cases collected from the literature at that time there were four in which a positive result was obtained at even longer intervals the longest being 91 days. A positive result therefore does not definitely establish the fact that the foetus is alive nor does a negative result definitely establish the fact that the foetus is dead. I have obtained negative Friedman reactions in three cases of threatened abortion. In one of these, tests performed before and after the time at which the patient was threatening to abort were positive though a negative result was obtained at the time of threatening. Prof James Young (*Brit med J* 1937 1 9-4) obtained negative pregnancy tests at times when the foetus was alive in over half the cases on which such tests were performed in his habitual abortion series. It is, I feel important that this point should be emphasised, for one is frequently asked to perform a pregnancy test to settle the question as to whether the ovum is alive or dead. The curve of oestrin excretion in the urine drops more rapidly than does the prolactin curve and an oestrin test is therefore of more value but still highly unreliable.

(2) In discussing the treatment of habitual abortion Miss Parkes is reported as advocating the use of "large doses of a substance stimulating luteal activity which was found in the urine of pregnant women marketed as Antutrin S or Progynon. Progynon is not a gonadotropic extract but the standardised preparation of oestrin marketed by Schering Ltd. It should not be used in the treatment of habitual abortion. Miss Parkes's reason for advocating gonadotropic extracts rather than extracts of corpus luteum is that the latter are unfortunately still very expensive. The price of 60 ampoules of progestin, each containing 1 mg (1 rabbit unit) as supplied by a certain firm is 142s. The price of 60 ampoules of the luteinising gonadotropic extract prepared by the same firm is 90s. if the strength of each ampoule is 100 rat units or 180s. if of 500 rat-unit strength which is the strength presumably referred to when Miss Parkes mentions large doses.

I am Sir yours faithfully

THE SEVENTH ENGLISH SPEAKING CONFERENCE ON MATERNITY AND CHILD WELFARE

To the Editor of THE LANCET

SIR.—The report of this conference in THE LANCET of June 12th states that "reprints of a brief history of the child welfare movement" written by me were distributed to the delegates and that this history did not mention the roots of the movement. May I say that my paper which was entitled the Present Position of Maternity and Child Welfare in the English-speaking Countries was not a history, but a brief summary of a large number of documents received by the Conference Committee from the United States, the Dominions and the British Colonies Protectorates and Dependencies describing what is now being done for the welfare of mothers and young children in those countries respectively. The paper began by explaining that the conference was the latest of a long series beginning with the national conference of 1906 which had its origin in a meeting of the British delegates to an international congress in Paris in the preceding year but except for those introductory remarks the paper was given up not to the past but to the present. What your correspondent specifies as missing, the

roots of the movement' are of course well known to students of the movement and are discussed in my book *The Early History of the Infant Welfare Movement*, published in 1933.

I am Sir yours faithfully

ANTIBODIES AGAINST HORMONES

To the Editor of THE LANCET

SIR.—In the leading article on p. 1471 of your last issue there is a statement suggesting that Collip and Anderson introduced the study of antihormones. Over thirty years ago I remember the late Sir Edward Sharpey Schafer stating that Swale Vincent also recently deceased had discovered a type of immunity to internal secretions. Writing on the injection of suprarenal extracts Schafer said concerning Vincent's experiments that "Doses insufficient to cause a fatal result produce immunity to larger doses which would otherwise be fatal and this effect may last a few weeks" (*E A Schafer Text Book of Physiology* Edinburgh and London 1898 vol. i p. 951). As both of these authorities have joined the great majority I feel that justice should be done to them as pioneers. Vincent's paper is I believe in the *Journal of Physiology* (1897 22 111).

REGIONAL ILEITIS

To the Editor of THE LANCET

SIR.—Gastro-enterologists and clinicians generally will be interested to know that Charles Combe and William Saunders a fellow of the Royal College of Physicians of London reported a case of terminal or regional ileitis (Crohn Braun type) before the College on July 4th 1896 131 years ago! The title of the report was A singular case of Stricture and Thickening of the Ileum.

The patient was William Payne George Esq. of a very nervous and delicate habit at necropsy (Monday Feb 10th 1896) it was found that the stomach, duodenum, the jejunum and the upper part of the ileum, liver, pancreas, spleen, and kidneys were in a natural and sound state. The lower part of the ileum as far as the colon was contracted for the space of three feet to the size of a turkey's quill. (*Medical Transactions published by the College of Physicians in London*, iv 16-21 1813 London.)

John Abercrombie (1780-1844) discusses pathologic states of the ileum and reports cases of terminal ileitis (Combe Saunders Crohn Braun type). On p. 263 of John Abercrombie's book *Pathological and Practical Researches on Diseases of the Stomach, the Intestinal Canal, the Liver and other Viscera of the Abdomen* (Edinburgh edition pp. 258-263 Waugh and Innes 1828 report Case (11) he tells of a girl, aged 13 about a year before her death began to be affected with pain of the abdomen and frequent vomiting. The lower end of the ileum to the extent of about eighteen inches was distended thickened in its coats externally of a reddish colour and internally covered by numerous well-defined ulcers varying in size from the diameter of a split pea to that of a suppurate. The lungs and all other viscera were healthy.

HYMAN J GOLDBSTEIN

Camden, New Jersey U.S.A. May 27th.

INDIVIDUAL PSYCHOLOGY

To the Editor of THE LANCET

SIR,—In consequence of the sudden death of Prof Adler at Aberdeen on May 28th it has become necessary to remodel the programme of lectures and vacation courses in individual psychology arranged for this summer. Dr Alexandra Adler, Prof. Adler's daughter and herself a brilliant exponent of individual psychology, has very courageously undertaken to carry out, as far as possible, the programme arranged for her father. Certain adjustments and cancellations have, however, been necessary and the programme now is as follows—

Lecture course, non resident, in the B.M.A. Hall, Edinburgh	June 21st–July 2nd
Vacation course at University Hall, Liverpool	July 7th–12th
Vacation course at Bishop Otter College, Chichester, Sussex	July 17th–26th

We, the undersigned, being convinced of the great value of individual psychology in throwing light on the fundamental problems of human life in an age of great perplexity, would appeal to the medical and teaching professions, and the Church and parents especially, for as large a measure of support as possible for these courses. This would be the finest tribute that could be paid to the memory of a great benefactor of the human race, who devoted his life to freeing men and women from the burden of misconception and misunderstanding which lies so heavily upon the human family.

We wish to take this opportunity of thanking the University and City of Aberdeen for having done everything in their power to honour the memory of Prof. Adler by arranging an official funeral service in the chapel of King's College on June 2nd.

We are, Sir, yours faithfully,

NINA HAMILTON AND BRANDON,

ALBERT LIVERPOOL,

ISABEL MARGESSON,

ALFRED BEIT,

METHODS OF DESTROYING BED-BUGS

To the Editor of THE LANCET

SIR,—Fumigation against bed bugs needs experts to do it. There are millions of bug infested houses which are unlikely to be fumigated for years, and it would be an advantage if we could suggest ways in which the inhabitants could at least keep down the bug population in the meantime. The only methods they can use are contact insecticides, and, as I suggested in my letter of June 5th, dilute methylated spirit may be useful in this way. While fully appreciating the improvements which Ashmore and McKenny Hughes have described in their article and recent letter I see no reason why the victims should have to wait until all local authorities have been persuaded to use 'heavy naphtha'.

I cannot understand why Ashmore and McKenny Hughes should say (*The Lancet*, June 12th) that "contact insecticides are helpful in dealing with a light infestation, but in our opinion a heavy infestation can only be dealt with successfully by a fumigation process." Surely any inefficient process—even soap and hot water—will do much damage in a really heavy infestation and so produce a light one. It is the light infestations (perhaps the remains of heavy ones) which are difficult to eradicate and

efficient fumigation which penetrates every crevice is the best method. Fortunately a light infestation causes less suffering in the house.

Contact insecticides can be used unknown to the neighbours, who always realise when fumigation is being carried out. The odour of heavy naphtha may be "not unpleasant," but the neighbours may be! There is still a stigma attached to having a bug infested house, even when it is a case of the "pot and the kettle."

University, June 17th

INFECTION THROUGH OLFACTORY MUCOSA

To the Editor of THE LANCET

SIR,—In reply to Dr Rake's request for further information (*The Lancet*, June 12th) all his difficulties are due to a slight acidity of the solutions he employs. Prussian blue is not formed when iron ammonium citrate and potassium ferrocyanide are mixed in faintly alkaline solutions. We still have some such solution made up July 4th, 1933, continuously exposed to light, which is crystal clear and with only slight deposit. It still contains practically all the ingredients in true solution, as shown by the amount of deposit on acidification.

Although Dr Rake's mixture contained granules it also contained some true solution, and the latter would naturally permeate easily, as demonstrated by Le Gros Clark. I am still unconvinced with regard to the passage of pneumococci from the nose to the subarachnoid space within two minutes, and I hope Dr Rake will continue his researches in order to substantiate this very important statement.

I am, Sir, yours faithfully,

F. A. PICKWORTH,

Director, City and University of Birmingham Joint
June 21st Board of Research for Mental Disease

PRESENTATION TO SIR FREDERICK HOBDAI

To the Editor of THE LANCET

SIR,—An appeal has been launched for funds for the purpose of making a presentation to Sir Frederick Hobday on his retirement from the position of principal and dean of the Royal Veterinary College, as a mark of appreciation of his services to veterinary science in general and the Royal Veterinary College in particular.

Sir Frederick has intimated his wish to devote the sum raised to the furtherance of the collaboration between the medical and veterinary branches of medicine in their mutual crusade against the diseases of animals which are common to, or communicable between, animals and man. Since the preliminary letters were issued the method of carrying this out has been considered by Sir Frederick and he desires to found a research scholarship fund in order to encourage research by veterinary and medical men in connexion with the diseases of animals and man. It is hoped that this will further the liaison between the two professions and be of great benefit to the science of medicine in its widest sense. The fund is to be called the Hobday Research Endowment Fund.

The committee feel that these details, and particularly the idea itself, will be of the greatest interest to members of the veterinary and medical professions. It is hoped that amongst his numerous friends and well-wishers a substantial sum will be raised which will be sufficient to enable this scheme to be carried out adequately.

I am, Sir, yours faithfully,

L. D. T. COX, Hon. Secretary

St Ermins Westminster SW June 19th

BRITISH ASSOCIATION OF RADIOLOGISTS SKINNER LECTURE

To the Editor of THE LANCET

SIR.—In the report of this lecture which appeared in your last issue the necessary compression has resulted in ambiguity with regard to some of the opinions expressed. I should be grateful if you would allow me a little of your space to clarify matters.

(1) The report states that I advocated the use of X rays after radical surgery and that I also consider surgical ablation valuable because of its psychological effect on patients. What I said was as follows

For practical purposes in this country we must assume that the primary growth will be got rid of by operation or by radium implantation. The latter saves the patient from what is rather unattractively referred to as mutilation and in the case of some women it is psychologically very desirable to avoid ablation of the breast. Others of a different mentality prefer as they say to get it over and done with; actual removal gives them a greater sense of security. I prefer surgical removal if it is not too drastic. An axilla in which the glands are not palpable is best left alone. If there is microscopic invasion, it can be dealt with by radiation.

(2) The report states that I do not consider Todd's treatment suitable for hospital cases but that I recommend it where there is metastasis in bone. I said that I did not consider Todd's method suitable

for use as a routine procedure in general hospitals, but reserved it for otherwise desperate cases of generalised metastasis in bone where concentrated X ray dosage was obviously impossible. For the single or at any rate non multiple, metastasis deep X ray treatment in the usually understood sense is certainly indicated—spontaneous fractures may be caused to unite and the patient restored to active life for months or even years.

I am Sir yours faithfully

F. HERNIMAN-JOHNSON

Brook street W., June 2nd.

THE FUTURE OF OBSTETRIC PRACTICE.—Dr ELWIN NASH writes. I notice that your report of my paper (published on p. 1285 of your issue of May 20th) states that in my district the average number of deliveries attended by doctors was six a year. Thus I was very careful to record was the result of a questionnaire sent out a few years ago to a large number of towns and represents the average number of confinements attended by medical practitioners outside an institution. It must be realised that there are still a number of cases attended by general practitioners in nursing homes of varying grades. Had I been present at the meeting this might not have got into print in this particular form. Unfortunately I was at the time a patient in hospital as the result of a difference of opinion over the right of way with a motor-car.

PANEL AND CONTRACT PRACTICE

The Essex Public Medical Service

The provision of medical treatment on a prepayment basis is becoming increasingly popular as is shown by the rapid growth of hospital contributory schemes, and the steady progress made in the establishment of public medical services for the treatment of persons who though not covered by the national health insurance system are in much the same economic class as the insured. At the second annual conference of public medical services last November it was stated that the number of services now working was 63 with approximately 404,000 subscribers and the organisation of such services has become a definite part of the activities of the British Medical Association. The thirteenth annual report of the Essex Public Medical Service recently published gives some particulars of the working of this method of providing medical care on a voluntary insurance basis. In 1936 the number of subscribers was 31,085 (adults 16,060 children 14,485) and the number of practitioners 274 of whom 30 joined during the year. The subscriptions amounted to £21,481 and the payments to doctors to £17,128, the largest amount collected for any one practice being £1283. The sum of £3467 was expended on collectors' commission and expenses and other administrative charges cost £1463. We note that among the subscribers the proportion of children to adults is becoming smaller. At one time it was nearly two to one but it has been diminishing year by year until in 1936 the adults outnumbered the children by 2115. This is attributed to the declining birth rate which as the Minister of Health pointed out in the House of Commons last week, will probably reduce the number of children attending public elementary schools by about a million within the next 15 years.

Understudying the Dentist the Sequel

Readers will recall the appeal of a practitioner who was disallowed his fee of 10s for attendance

late at night, on a bleeding tooth-socket following extraction. The Minister allowed the appeal not on any ground put forward by the practitioner but on the technical ground that the insurance committee had not obtained a formal expression of opinion from the local medical committee that the service rendered was within the scope of medical benefit. That has now been done and the proper tribunal has stated that the service was within the scope. The Minister being informed of this remarked in effect that it was now too late. The matter having been dealt with by the insurance committee and adjudicated upon by him on appeal was now *res judicata* and he was therefore precluded from taking any cognisance of the report now submitted under Regulation 46 (4). The medical benefit subcommittee not unnaturally are displeased about it. They have caused the Minister to be informed of their opinion that in a case of lapse in procedure not of substance it is desirable that an opportunity of rectifying the procedure should be afforded rather than that the appeal should be allowed on the ground of that lapse alone. Accepting the position as now irremediable the insurance committee decided to return the 10s to the insured person from their general purposes fund subject of course to the Minister's consent. Dr V. is therefore not out of pocket for his successful effort to focus attention on the relation of dental work to the medical practitioner's capitation fee.

¹ *Lancet* Feb. 6th p. 34

CORONATION GIFTS FOR HOSPITALS.—The trustees of the Albert Lever Benevolent Fund are allocating £10,000 to be divided among twenty selected hospitals as Coronation gifts. Among the institutions which will receive them are St. George's Hospital, the Royal Free Hospital, Westminster Hospital, and the Chelsea Hospital for Women.

OBITUARY

SIR SQUIRE SPRIGGE

1860-1937

EDITOR OF "THE LANCET"

Sir Squire Sprigge died at noon on Thursday, June 17th. He was at the office as usual up to Coronation Day, and his death—from pulmonary embolism following an operation—came unexpectedly.

"For the convenience of *The Lancet* sexton," as he put it, he had left among his papers an outline of his life, but it was a bare outline.

BOYHOOD AND PURSUITS

Samuel Squire Sprigge was born on June 22nd, 1860 at Watton, Norfolk, where his father, Squire Sprigge, was a doctor and small landowner. His father, after taking distinction in surgery, had settled in Norfolk and became widely beloved as a general practitioner who was interested not only in the maladies but in the lives of his patients. The family was indigenous in East Anglia for the elder Squire was the eleventh child and youngest son of the Rev James Sprigge, D.C.L., rector of Brockley, Suffolk, a family living, and his wife was the daughter of John Jackson, solicitor, of Dutton Hill, Bramtree, and Bury St Edmunds. His eldest son, Samuel Squire, had his early schooling with the Rev J. R. Pilling at East Dereham before going to Uppingham and Caius College, Cambridge, where many of his mother's family had been before him. At Uppingham he came under the influence of Thring as head master, and in the Lower VI he met G. Herbert Thring with whom his friendship was lifelong. "Neither of us," his friend admits, "was a hard worker, but Sprigge always showed a very quick power of grasping and learning." He could not be kept there long enough to get into the highest form or into the cricket eleven or Rugby XV, but he was a sound player at both, alert in his movements and "terribly fast on his legs for so small a man"—a quality that later brought him success as a fencer. On his father's death in 1877 his mother moved to Bury St Edmunds where Squire played regularly for the city cricket club and was well known in the football field, he played for Suffolk on many occasions, and later for Norfolk and Middlesex. Among his papers is a newspaper account of a lively association match at West Ham Park between Middlesex and the Norfolk County Club in which it is recorded that "Sprigge at centre forward was enabled to place the first goal of the game to Norfolk."

From Cambridge he entered St George's Hospital or "The Corner," as it was affectionately termed, and was popular as a shrewd student who could sum up a situation in six witty words. He was always immaculately dressed and his charm of manner endeared him to everybody although he kept company mostly with the Cambridge men. For two or three years he lodged with Thring, and their rooms were the centre for St George's men to collect. There was a good hand of whist and a mild gamble at loo. The party often included Hewitt Bolton, Sisler, Joseph Farrer, John Hunter and Weldon, and after tea they might go on and dine at Victoria Station. Sprigge clerked for Timothy Holmes, and their sparring was a source of delight at Thursday consultations. His memory was more than adequate to give him a profound theoretical knowledge of medicine and it was by virtue of this rather than of

clinical acumen that he faced examiners who, it is believed, were sometimes a little overawed by his knowledge.

It was at this time Sprigge began to write stories and cultivate the arts. His taste in books became wide, but he liked a good plot and "took great joy in the perfection of a gem like short story." He knew Dickens almost by heart, and enjoyed Wilkie Collins, Gaboriau, Sterne, Balzac, Henry James, de Maupassant, and in due course Edgar Wallace (at his best). Likewise he cared for good food, having high standards of simplicity, and knew well the points of wine, especially claret and burgundy. These tastes went with an expert's interest in moths and butterflies—to the end of his life "he used to point like a dog at the sight of an interesting looking one"—and later a love of gardens. His town garden was made as much like a country garden as possible. He was especially proud of his herbaceous border. Appreciation of colour and form led to his becoming, in the last twenty years, a keen amateur of water colour painting, and he was at all times an informed critic of architecture. In early days at the Savile Club his chief associates were Edmund Gosse and William Hunt the historian, and Rudyard Kipling, Rider Haggard, Anthony Hope Hawkins, Max Beerholm, and William Rothenstein were to become his friends.

INTRODUCTION TO JOURNALISM

After graduating in medicine at Cambridge in 1887 he made no bid for a resident post at St George's, of which there were then only four in all, but went on to the West London Hospital and Brompton where he worked under Percy Kidd, also an old Uppingham boy, for whom he had a great admiration. He did some medical reviewing and medical writing, mostly in lay papers and anonymously. He also wrote a good many short stories in popular publications, but had formed no plans for the future when two very different openings presented themselves, and it happened that he could avail himself of both. One was the post of secretary to Sir Russell Reynolds, afterwards president of the Royal College of Physicians of London, whom he assisted in the preparation of literary work which was unfortunately never completed. His experience at this time behind the scenes in a famous consulting room gave him, however, the insight into the attitude of mind of the practitioner as he goes about his work, which later found expression in a remarkable chapter in "Physic and Fiction" (1922) entitled "the pathologist in the street."

The other opening came from an introduction to Sir Walter Besant, the acquaintance soon developing into a warm friendship, and he became secretary to the Society of Authors, working there in the afternoons and with Sir Russell Reynolds in the mornings. Together Besant and Sprigge produced two pamphlets, now out of print on the cost of production and the methods of publishing and these formed the basis of the society's programme. Sprigge's force and ability combined with Besant's burning zeal gave the society a start which it has never lost. The novelist and his junior represented the society at the Chicago Exhibition in 1893 and were both freely caricatured in the American papers. It was in Chicago that Sprigge received the telegram which determined the course of his life. Mr T. H. Wabler who had noticed his writings offered him a responsible

Guere Guage

post in the editorial room of *The Lancet*, and he returned at once to London to begin work which he never laid down. But having resigned the secretaryship he long remained a leading spirit in the counsels of the authors society and in 1911 when the Copyright Bill was being promoted he was elected chairman in succession to Maurice Hewlett. In December of that year he presided at a dinner at the Criterion to celebrate the passing of a Bill described by Mr Conyns Carr as the largest instalment of justice which Parliament had ever given to English literature. The presence at this dinner of Sir Frederick Macmillan was evidence said the chairman that the Society of Authors could no longer be described as a ring to fight the publishers. It was an earlier stage of this Bill which led to Sprigge being interviewed by the *Pall Mall* on an event which evidently gave him pleasure for he wrote "my first interview" on a cutting from that journal.

EARLY DAYS AT THE OFFICE

After a short probationary period Sprigge became assistant editor of *The Lancet* which was then under the joint control of Mr T H Wakley F.R.C.S. and his son Dr Thomas Wakley Jun son and grandson respectively of the founder of the paper. They were advised by Surgeon-General Jeffery Marston Dr Sydney Coupland and Dr James City Glover and Sprigge has publicly recognised the excellence of the early training he got from these advisers and from the younger Wakley his immediate chief. In 1907 the senior editor died the junior surviving him by only two years, and in 1909 at the age of 43 Sprigge was promoted to sole editorship and was free to develop his special interests. One of these was medical education. From the moment he entered the office he began to attend the sessions of the General Medical Council, and made a daily study of the regulations of universities and colleges in regard to the training of students. Foremost in his mind was always the training of the student on broad cultural lines and the reform of the curriculum so as to avoid overburdening him with detail. He began as was his wont to expound his ideas to a trusted secretary waiting for an occasional comment to which he would reply with further long expostions. This was always the way in which he worked out his ideas, and then he would sit down and write rapidly and unceasingly page after page often racing up and down the tortuous stairs of the old office when a fresh idea came into his mind which must be set down without delay. Some of these early thoughts were crystallised in the address he gave at the opening session of St. George's Hospital medical school in 1910 in which he discussed on the award of prizes and scholarships. These had their place as an incentive and no more. The modern conception of medicine was that all men in whatever walk of life they were practising should see their life as one long education. He protested against the multiplicity of examinations and their intricacy and pleaded for the wider endowment of teaching. Only short-sightedness and a false economy encouraged students freely with exhibitions and scholarships while making scanty provision for those who taught them. What was needed he said voicing an opinion now but not then generally held was professional chairs for the teachers and he appealed to wealthy and generous persons to found these chairs. "What right," he asked, "have we to expect that the highly endowed student will receive adequate instruction if we fail to endow his masters?" A paper which he read in Paris at the First International Congress of the Medical Press in 1900 set out

what became the policy of *The Lancet* towards medical education. This took more precise form in a modest volume entitled *Some Considerations of Medical Education* which appeared in 1910. The main theme of this book is that while the education of the medical student in this country will bear favourable comparison with that in any other country it is an anomalous state of affairs that the diploma giving permission to practise is in no sense an accurate measure of the soundness of his training. Another series of anonymous articles on the relations of medicine to the public was also republished in book form. These articles were reconstructed as a thesis for a belated M.D. degree at Cambridge.

Sprigge had as his first assistant at *The Lancet* Dr H. P. Chalmers, a historian and scholar, their collaboration though congenial lasted only two years in that form. In 1911 Dr N. Gerald Horner now editor of the *British Medical Journal* joined the staff but here again the association was short for on the outbreak of war in 1914 Dr Horner went on active service and the editor brought out the journal single-handed until Dr Egbert Morland came to the office in 1915. The war reduced *The Lancet* to small proportions but care was taken to use its pages to the best advantage and Sprigge was in constant and intimate contact with the Army medical authorities. He found time also to make a useful contribution of his own to the care of those in distress for the Belgian Doctors and Pharmacists Relief Fund, started in 1914 was run from *The Lancet* office with Dr Harold Des Voeux as treasurer and administrator and the editor as secretary. Over £25,000 was collected—much of it through the help of Sir Dawson Williams and the British Medical Association—and large quantities of clothing were distributed while hospitality of all sorts was secured and professional openings were found for refugee doctors unable to serve with the Forces.

Some of his later outside activities should receive mention here. Having with expert collaborators done much in *The Conduct of Medical Practice* (1927) to instruct medical men and women how to protect themselves from unjust attack and how to avoid giving occasion for attack he was invited to become a vice president of the London and Counties Medical Protection Society. Later he became a trustee of the society's reserve fund placing at the disposal of its advisers his exceptional knowledge of affairs. His interest in education naturally extended to the public school which attracts so many sons of medical men and for twelve years he was a member of the council of Epsom College doing much both personally and through the medium of *The Lancet* to promote the interests of its Royal Medical Foundation and the improvement of its school curriculum. When the Coal Smoke Abatement Society initiated its first serious inquiry into atmospheric pollution Sprigge put *The Lancet* laboratories at its disposal and published its reports when no scientific journal was willing to take them. He was a vice president of the London and National Society for Women's Service and took a special part in the development of its junior council often attending their meetings and always standing their friend.

In 1921 Sprigge was elected F.R.C.S. Eng. and in the same year received a knighthood. In 1928 he went to the United States to deliver the annual Hunterian lecture of the American College of Surgeons and while there was made a fellow of the College. *The Lancet* had already profited much from his many visits to the Continent and at the instance of the

proprietors he visited a group of the best known American and Canadian universities, investigating their medical curricula with the object of making it easier for medicine to coöperate across the Atlantic. A report of these visits was published as a special supplement of *The Lancet* and the report and lecture are the only contributions which have ever appeared in the paper under his own name. It was only in the index that his authorship of the notes "From a Chronicler" (December, 1936) was revealed.

In 1927 he was elected F R C P Lond

TWO CENTENARIES

Soon after Sprigge joined the office he was commissioned by the Wakleys to write a history of the founder of *The Lancet* and of the early work of the paper. In Sprigge's hands this developed into a connected story of *The Life and Times of Thomas Wakley*, who was born just a hundred years before this memoir of him. The biography in its serial form occupied his week ends for many months, each chapter being revised and completed in the train to and from Aldeburgh. The second centenary of which Sprigge was the chronicler was that of the foundation of the journal itself, nearly 30 years later he retold the story of medical progress in Wakley's time and brought the centenary issue of *The Lancet* up to date in what might be truly described as the life and times of Squire Sprigge. At the centenary dinner, held in November, 1923, addressing a gathering which included most of the leaders of the medical profession, he assured them that "the past outrageous energies can never be repeated by us the violence of past days is gone, but the desire for the right and the zeal to achieve it remain as forcible as they were a hundred years ago." And he went on to describe *The Lancet* as a friend made paper, relying on the good offices of its supporters who read each other's wisdom and clarify or correct each other's views. "I also," he added, "am a friend made man. Through school, college, and hospital associations I have exacted levies from friends and, as time went on, enlarging environment gave me enlarging opportunities for such exactions. It is to others I owe what you have accorded to me. Any measure of success which has been obtained has been in return for labours of love. It is they who have to discharge a dull routine and face distasteful duties whose devotion is really admirable. I have enjoyed myself. Medicine may be only one section of the world's activities but it is an ever developing and all permeating one. It has been my delightful duty to record the phases and ramifications of medicine as they are produced and as they are justified by the workers themselves." This second centenary came after the ownership of the journal had passed to Messrs Hodder and Stoughton, but the continuity of policy was evident when Sir Ernest Hodder Williams, then the chairman, recalled at the dinner a pledge made by the new proprietors to maintain the honoured name of the paper "even though it should mean—as in the case of Wakley—having our houses burned down and gutted, even if it means we have to fight half a dozen libel actions in as many years."

DEPARTMENTAL CONTACTS

The successful conduct of any journal depends on the harmonious working of the several parts—the office, the printing house, the advertisement department. It was Sprigge's good fortune, for which he was himself largely responsible, to be associated over long years with departmental chiefs on terms of

intimacy. Until the move from the old house in Bedford street across the Strand to the Adelphi the composing room, three floors above the editorial room, was ruled throughout his time by two men, father and son. The latter, who is still "the printer," writes "At the period when the typesetting of *The Lancet* was done in our own offices Sir Squire was exceedingly popular with the readers and compositors, who to a man would work with great enthusiasm when a big article arrived barely in time to be inserted in the current issue (at this time the type was hand set). Sir Squire deeply appreciated this help, and in return took a personal interest in the staff and remembered the varied characteristics of the men, whose future careers he took great pleasure in discussing for years afterwards. Should further advice be needed in cases of illness he would gladly make the necessary arrangements. Also at Christmas he would devote a sum of money to purchase a present for each man, consisting of a pipe, tobacco or cigarettes. The juniors, whose job it was to carry copy and proofs to and from the editor and the printing department, found that he was never too busy to enjoy a joke. For instance, on a certain Boat Race day the messenger wore a large Oxford favour in his coat when he carried proofs down to the editor. 'I can't be bothered with you to day,' said he, with twinkling eye, 'you must hand them to Dr Cholmeley (an Oxford graduate)'. In the early part of the war he had to work without the aid of a sub editor, but the printer's readers came to the rescue and helped him to put the copy in proper order. Altogether his was a great and lovable personality, and he found no difficulty in arousing the interest and enthusiasm of those fortunate enough to work with him."

Here are a few impressions from a member of the office staff who "had the pleasure of knowing Sir Squire during 45 years at *The Lancet* office. From his early start he endeared himself to all, being ever willing to help and advise. In fact he never tired of doing good. Anecdotes about his resource are many, but one must suffice. On one occasion a man who called to subpoena him to give evidence, being told he had not arrived, announced a determination to wait outside for him. Sir Squire, wishing to get away, sent the office boy to buy a cap, put it on, turned his coat collar up, and walked out past the waiting man, leaving a truthful message that he had gone to an inebriate's home (of which a friend was superintendent).—Sir Squire Sprigge was both good and generous. We all loved him and we shall sorely miss him."

"He was kindness personified," writes the Manager. "It will always be a cherished thought that I was privileged to have been associated with him for seventeen years. During the whole of this period, and particularly the last eight years, there was never a difficulty, either of a business or domestic nature, in which I did not know I could ask his counsel and readily receive the guidance needed to surmount the obstacle. In my absence from the office on holidays his help was constantly available in business matters. His great human kindness and foresight were always available for the solution of problems, large or small. The charm of his personality affected senior and junior alike, and especially those who had suffered loss or misfortune were helped by his presence and by his manner."

THE EDITOR

An editor is necessarily a journalist, but the two rôles are not the same. Sprigge was less modern

in technique than in policy. His prose was leisurely and unemphatic; at its best it was rich and charming but he did not strive to put his meaning into words of one syllable and he sometimes deliberately weakened his argument by a qualifying phrase that sounded like an afterthought. He was content, in fact, to develop his ideas in dignified English with reservations in parentheses whereas the journalist of to-day conscious that the world is full of distractions seeks first to engage and keep his readers' attention. Characteristically Sprigge despised the tricks of his trade—the attempts to catch eye or ear. He did not much care whether a page looked formidable or readable. He seldom baited his articles with ingenious headings, but liked them to have plain descriptive titles. In a word, he was not at heart a propagandist. Equally fundamental was his disinclination to alter argument or narrative for the sake of a good phrase or a witticism which meant that his professional essays were less entertaining in type than they were in draft. Similarly as an editor he never attacked for the pleasure of attacking. When a junior suggested gloomily that the function of a leading article was surely to lead he replied accurately enough that the word leader merely indicated an article in which the lines are loaded or spaced.

It has been said that he was a typical English gentleman in his shyness of showing personal emotion or of touching in conversation upon serious problems.

The emotion was there however carefully concealed and his truly tender concern for the interests of others sometimes broke through his self-control. The same applies to his behaviour as an editor. Though he took pride in the influence that *The Lancet* might exert on medical affairs and was anxious to exert it sanely and wisely he felt no temptation to go out to look for windmills on which he could demonstrate his skill and thus enliven his pages. But his feelings on medical and public affairs were none the less real because he sought to suppress them, and the indignations or sympathies of his liberal mind occasionally found forcible expression.

In selecting material for publication he preferred the contributions of men who worked in an environment of criticism at hospital or elsewhere. But his personal contacts were not confined to the conventionally successful and he knew well that good sense could be spoken in strange tongues. He wrote once to an assistant: "You are too forthright. Boundaries do not always bound boasters; do not always lie the third-rate person sometimes produces second-rate stuff. He showed perspicacity in seeing what people were fit for and in not attempting to make them do more. He once said: 'Never take away a man's vanity. If you do that he's done for'."

He disliked arm-chair medicine but his general outlook did not conform with the definition of an editor as "a man who keeps things out of a newspaper." Where a member of the profession had earned a right to be heard he would often take great pains that he should be heard effectively. If it was folly to insist on speaking to the editor himself over the telephone—which instrument he never learnt to control—it was very wise to call and secure recognition as a person rather than a signature. As an editor he had catholic tastes. If he did not interpret free speech as meaning that the columns of *The Lancet* were open at all times to letters on controversial subjects it was because he knew how hard it may be to deny the claims of interested parties to replies that lead nowhere. Ultimately the

editor must decide what he wants to put in his paper and as an editor Sprigge's highest qualification was that he knew his own world—and also much of the world outside it. He was a familiar and a much beloved figure at the United University Club as well as at the Athenæum and was often consulted about new developments while they were being planned.

It is useful that an editor should have private knowledge of events but here in later years, he resembled C. P. Scott of the *Manchester Guardian* who occasionally omitted to mention his special knowledge until it was too late for his staff to make use of it. What he did provide all the time however was an eye for errors large or small, and a judgment based on knowledge of men and it was a mature and sagacious judgment. Like Scott again he had a low opinion of his readers' capacity for appreciating irony but in other respects he felt himself representative of the plain medical man faced with advancing science. "If I can understand this," he said, "so can any of our readers." He strongly objected to any suggestion that special fare should be provided for general practitioners as a class apart. His journal was for the medical profession, all of whom had the same basic training. At the same time he tried to prevent its becoming what he called too pathological. His highest praise when his advance copy of *The Lancet* arrived on Thursdays and he exchanged cigarettes with the printer—an invariable custom—at his morning visit was that its contents were all over the place. If this favourable verdict was sometimes associated with regret at the inclusion of material that he personally found unreadable the regret remained unspoken. For his modesty led him to drive his team with the lightest of reins and those who worked with him will remember that he gave them all the freedom they wanted, criticising rarely and holding himself responsible only when things went wrong. In recent years the inside medical staff of *The Lancet* has consisted of the editor and four assistants who shared one large room. Though their ages ranged from 26 to 76 sectional division of the work was avoided: each was encouraged to tackle any aspect of it and submit to robust comment on the results being in turn expected to use his knowledge in criticism of the efforts of his colleagues. The fact that the chief did not pursue consistency in detail made it easier for him to delegate tasks to others. The tradition he established was that all were working for *The Lancet* not for the editor.

But these apparently simple solutions came from a complex mind. He liked to follow custom but did not readily remember rules even when he had made them himself. He was no enthusiast for policies. He was true to national type in his opportunistic outlook and ability to compromise. The opportunism however was that of a philosopher and the compromise those of a diplomat. He often followed the classical advice to give a decision without the reasons for it. Nevertheless his office was a school of the diplomacy of which he was a master. His anger was not always righteous but his associates learned to know that irritability was sometimes assumed so as to put an artificial end to discussion that tended to be too protracted. Moreover he usually managed to make it appear impersonal directing it at objects and subjects rather than at persons. His mood could change as quickly as April weather. But sly and cheerful blunt or bland he had an uncommon air of breeding and no one seeing his fine and fearless face could doubt either his wisdom or his power to manage others.

THE TRUSTEE

In 1894 Sprigge succeeded to a small family property in Buckinghamshire, and in the following year he married Beatrice, daughter of the late Sir Charles Moss, chief justice of Ontario. There are two children of this marriage, Mr Cecil Sprigge (financial editor of the *Manchester Guardian*) and Mrs Mark Napier (Elizabeth Sprigge the novelist), and five grandchildren. In 1905 he married Ethel, daughter of the late Major Charles Jones, and she survives him. His second daughter, Annabel, is a sculptor.

He was thus the centre of a large family circle, going down to the third generation, but he was also trustee for many outside it, and trusteeship of one kind and another made up a large part of his life. He held in trust the assets (not only material) of many who had no claim on him save that of a common profession, college, or school, for the impulse to confide in him was widely felt. So sure was his touch, so wise his discretion, that no awkwardness or embarrassment came to mar future relations. He did not ask sympathy in return, indeed he would mostly have resented it. He was taciturn about his own troubles and worries. But his hand was always ready to be outstretched, and his purse to be opened, to friends or even acquaintances in difficulties. Chivalrous is the word used of him by some German friends in whose house he often spent his summer holidays. All his ingenuity was often taxed to find means by which he could avoid being thanked.

To the casual observer he may not have appeared a patient man, but in fact one of his outstanding qualities was his patience—patience with the follies of a large number of men and women who came to him for help and advice, but particularly patience with the vagaries of the young. Responsibility had been early thrust upon him, for he was only at the end of his school days when his father died and he was left as eldest son of a young family. The sense of family obligations was, and remained, imperious in him. He viewed the small estate he later inherited as a trust vested in the head of the family, carrying with it the privilege and duty of active interest in the well being of a considerable number of people, young and old. No man, however, could have been freer from the reproach of laying down duties for others, and though he might often have imposed his will upon the young he preferred to offer his help in whatever course they should choose, even (or more particularly) if it were not the course which he would have had them pursue. Indeed he respected personal independence to the point of appearing sometimes to abdicate authority. But he had usually chosen his ground well, and by allowing free play to others secured all the more surely their affection, and, at the really critical point, their coöperation.

Whatever he undertook to do, whether it was a task in the public service, a matter of necessary private business, or a study for delight or ornament, he performed with precision and energy yet with no inhuman airs of self dedication. As a well balanced human being with a fine taste in intellectual principles and in conduct he was a reverent inquirer into meanings rather than a confident assessor of opinions about first and last things. He had been born and brought up a country lad, and yet his lot was to work for half a century in the centre of a great town and to become a loyal and even a passionate Londoner. Always in the back of his mind he had the broad fields and the trees and a village church like that where he was laid to rest last Saturday. A single wreath sent

anonymously bore the words "In long memory of Sir Squire Sprigge. To know him was to gain strength."

IMPRESSIONS

Some idea of the effect of Squire Sprigge on his contemporaries and juniors may be gained from the selection of personal tributes which follows.

Sir Charles Sherrington—To contribute a few sentences in appreciation of Squire Sprigge, my friend and old fellow collegian, to your columns, which were so long his, comes, although it has its sadness, as in some sort a satisfaction. It may seem odd but my memory's picture of him at Cambridge mostly recalls a figure, characteristically well dressed, bound for the football field or the tennis courts, and, even in flannels, something of a Beau Brummel—but in the field or court a formidable hard bitten player. He was a general favourite with us all, witty and companionable, one who never seemed to have any particular work to do.

Meeting him later in London after he had joined his hospital I found a talk with him always an intriguing change from what I met elsewhere. I fancy he already moved in circles where the literary work of the day with its artistic and its business vicissitudes was constantly uppermost. At that time he would seem to me so detached from the interests of a medical school that I supposed he would drift off altogether. Later still I met him at a friend's house in Toronto, and Toronto seemed to him almost a second home.

I cannot trust my memory as to how long it is that he had been identified with the editorial work on *The Lancet*, but almost from the very earliest of my own personal contacts with the editorial office it was with Sprigge that my contacts had to do, always to find myself impressed, and indeed charmed by his ability, his geniality, and his helpfulness. In more recent years a scene which remains vividly to me is the commemoration banquet organised by him in celebration of *The Lancet's* centenary. All the world was represented. The speeches went on well beyond midnight. Everybody felt it a great success, and the presiding spirit throughout was personified in Sprigge.

Others will pay tribute to other sides of his versatile personality than those it was my privilege to know. To me his memory remains as that of a life long friend, whose gifts and character were such as often to raise in me the wish that good fortune might yet more than it did throw me in the way of his society and fellowship.

Dr Alfred Cox—It needs a great effort to imagine *The Lancet* without Sprigge, for, as must be the case with all great editors, he impressed his personality on every page of it. The sense of loss that our profession will feel on hearing of his death will be specially felt by those of us who knew him in his younger days when he was such a prominent personage in literary as well as in medical circles.

I had my first contact with him in the late 'nineties, when as an ardent medical politician I was much concerned with the abuses of medical contract practice. *The Lancet* had commissioned Mr Adolphe Smith to visit various parts of the country and write a series of articles on "The Battle of the Clubs," in which the sordid horrors of that branch of practice were exposed in a masterly fashion worthy of the best *Lancet* traditions. Sprigge wrote to me and asked me to help Smith in his investigations on Tyneside, which I willingly did. The effect of those articles was

profound not only on the outlook of many active doctors of my generation but on the subsequent policy of the British Medical Association. Occasional correspondence with Sprigge followed but it was not until 1900 that I first met him on a memorable occasion. At that time there was much dissatisfaction with the inertia of the B.M.A. with regard to the interests of the general practitioner. A body of us got together and a small deputation of which I was one was sent to ask Sprigge if *The Lancet* would put itself at the head of a new body and become its official organ. The interview was specially memorable to me because Sprigge, after listening to us very sympathetically, took the line I had persistently advocated. He said it would be a great mistake to do anything to weaken the one great organisation the profession had and told us we could come back if we liked, but we must then be in a position to convince ourselves and him that it was impossible to get the B.M.A. to do what we wanted. The result was well known. His attitude then as I found later was characteristic of the man. Proud as he was of his journal and always anxious to extend its influence, he always tried to take the long view of what was best for the profession as a whole. Many times in my official career I sought his advice and help and never in vain. He was sometimes critical of the policy we were pursuing and said so quite plainly in private at any rate. But he was ready to back us up with all his power when he knew we were right and he occasionally took considerable risks in doing so. Many a time he used his great personal influence behind the scenes, with prominent public men in order to further our objects. This was notably so during the Insurance Act fight and in connexion with the recruiting of doctors during the war.

His action in joining the Editor of the *British Medical Journal* to found the Medical Insurance Agency should not be forgotten. That useful and prosperous institution owed much in its earlier days to the support given by *The Lancet*.

It was with surprise, but great pleasure that I found on joining the staff at the B.M.A. that Sprigge and the Editor of the *B.M.J.* were on cordial terms. They were both strong men and liked and respected each other. It is easy to imagine how much less unity and good feeling there might be in our profession had the situation been otherwise. I remember Dawson Williams telling me when after the war both he and Sprigge were knighted that his pleasure in the distinction was greatly increased by the fact that Sprigge's good work had also been recognised. There can be few such examples of loyal and cordial cooperation alongside honourable rivalry in the history of journalism.

Sprigge was a delightful companion, genial, witty and humorous. I have heard him make one or two of the best after dinner speeches in my recollection. Few men can have been more utterly devoted to their life's work or prouder of it than Sprigge was, and I am glad that when the end came I found him still in harness. He carried on and improved the great Wakley tradition and in saying this I fancy there could be few things Sprigge would more gladly have heard. I am grateful to have this opportunity of paying a tribute to the Editor I respected and to the man it was a privilege to call a friend.

Sir Humphry Rolleston—Squire Sprigge and I first met in 1883 in the final of the Hospital Rugby try, played on the Half Moon ground, Putney long ago built over when he was playing for St. George's Hospital which on that occasion lost to St. Bartholomew's.

new Hospital.¹ Sprigge had just come up from Corpus College Cambridge and was slight and light but quick as a forward, especially in the Rugby football of those far-off days. Essentially a cultivated littérateur, probably few of those who knew him in his later life only would have guessed his earlier athletic activity or perhaps have read his two books long out of print, in a vein much lighter than some which followed about medical education. These were *Odd Issues* (1898) and *The Industrious Chevalier* (1902) collections of stories charmingly told, and drawing some of their local colour and incident from his life at Cambridge and St. George's Hospital. His *Life of Thomas Wakley*, his predecessor in the editorial chair of *The Lancet* and his work on the autobiography of Sir Walter Besant with whom he was closely associated were fine pieces of biography. With an exceptionally wide acquaintance with medical London he was a shrewd judge of men and manners and could have written an extraordinarily interesting account of the last half century, possibly he has yielded to the suggestion of friends that he should record his observations. His great work was at *The Lancet* and, with Sir Dawson Williams of the *British Medical Journal* who died in 1928, he exerted a memorable, though unobtrusive, influence on medical journalism in this country. Like Delane of the *Times* he was a man of the world with many friends; an interesting and arresting talker and leaves a gap it will be indeed hard to fill. But he had trained a number of his assistants on his own lines who will thus be able to carry on the fine tradition of this doyen of British medical journalism.

Sir Farquhar Buzzard—The death of Sir Squire Sprigge means at any rate to a large number of his contemporaries something more than the loss of a friend whose personal gifts and qualities were peculiarly distinctive and attractive. The experience of many years, a real test of general opinion has given us an almost blind confidence in the management of the journal for which he has been responsible and which largely owing to his able direction has become an essential and outstanding feature of our professional life. The news that *The Lancet* has lost its editor cannot fail to make us realise suddenly and perhaps for the first time how satisfied we have long been with the knowledge that the control of its policy and of its contents lay in his safe and masterly hands. One cannot doubt too that Sprigge's immutable loyalty to the highest traditions of the profession and to the interests of the public was always a great contributing factor to the mutual consideration which has distinguished the friendly rivalry of *The Lancet* and the *British Medical Journal*. There could be no better example of two parallel enterprises conducted with signal success and without resort to the unworthy expedients of journalistic competition.

The respect in which Sprigge was held by the two professions he adorned was based on his intellectual ability and integrity; the personal affection with which he was regarded by his many friends had its origin in his modesty, his generosity and his kindly but keen sense of humour. His services to the art and science and literature of medicine were performed silently behind the scenes and therefore difficult to record or assess, but their great value was indisputable and worthy of our homage, our gratitude and our memory.

¹ A contemporary tell us that Sprigge's consent on Rolleston's election to the staff of St. George's was "I'll meet him well as a vicious Dart & forward."

Sir D'Arcy Power—He was a great editor and many of us have watched with interest the numerous changes he made so unobtrusively whilst he occupied the editorial chair—changes always for the good—until he brought *The Lancet* to its present position. It is a journal which appeals alike to the professional and the non professional reader.

His death carries my mind back to a far distant period. As long as I can recollect my father—Mr Henry Power—paid a weekly visit to *The Lancet* office, then in the Strand at the corner of Bedford street, and brought back two or three books for review. They were, I was told, laid out on a table and each took what he fancied. The books were not returned and my shelves still hold a complete set of Darwin's works with "review copy" stamped inside them. What was paid in cash I never knew, but every Christmas a barrel of oysters arrived with Mr Wakley's compliments and good wishes. The oysters in later years were replaced by a huge home grown turkey bringing the compliments of the season from Tom Wakley. Once on a day never to be forgotten we found ourselves with our noses flattened against the first floor window of *The Lancet* office with a magnificent lunch in the room behind us, in front a glorious cavalcade, for Albert Edward, Prince of Wales, was on his way to St Paul's Cathedral to return thanks for his recovery from an attack of typhoid fever. The day, therefore, was Feb 27th and the year 1872. Alas! all have passed away. The medical members of the Wakley family, Dr Buzzard, Dr Sydney Coupland, Dr Glover, my friend Dr H P Cholmeley, quiet, capable, and scholarly, and now Sir Squire Sprigge. It is the penalty of age and Virgil was right when he spoke of tristis senectus.

Dr R A Young—Sir Squire Sprigge was a man of outstanding personality, with a wide range of knowledge and a clear perspective. He was quick to appreciate ability, intolerant of shams and of ineptitude, but with a deep sympathy for his fellow man in distress or difficulty. He had a very quickly acting mind, with an almost intuitive grasp of the crux of any problem submitted to him. He was a good, attentive listener, where his interest or his sympathy was aroused, and would often at once suggest a solution of a difficult problem or point out the fallacies in its presentation. His position as editor enabled him to watch and to assess the progress of medical science and practice, and he often showed a remarkable perception of the importance of new discoveries. He had a more profound knowledge of the persons and personalities in medicine than almost any man of his time. Such qualities and such experience combined to make a great medical editor, interested not only in medicine as a science and in the art of practice, but always keeping in mind the relations of medicine and medical men to the State and to the common weal.

He wrote easily and in a happy, clear, literary style. His comments were often as keen and as incisive as his editorial mind. He had the rare gift of constructive criticism, and he could quickly rewrite or reshape an article with good material ill presented, which most editors would have discarded. He was a kind and generous host, and with his wide general culture and great artistic gifts he was always interesting and illuminating. He had a keen and sometimes caustic wit, but it was never unkindly. The high standard of medical journalism in Great Britain owes much to his constant watch on the contributions to *The Lancet*, to his avoidance of the sensational, and to the sanity of his policy. The best tribute to him

is the esteem in which English medical journals are held not only in the profession but by the general public, and that not only in this country.

Sir George Newman—The death of Squire Sprigge comes as an unexpected blow to me. One always thought of him as young, alert, and virile. He was, with his great contemporary, Dawson Williams, one of the lights of modern English medicine. It is difficult for the younger generation of medicine to realise what these two men did for the profession and for the public. *The British Medical Journal* and *The Lancet* owe much to their respective proprietors and publishers, but they would be the first to recognise that their two famous editors made the papers what they became. Both papers have rendered a unique service to medical science and to the profession. Squire Sprigge brought to *The Lancet* his own peculiar intellectual gifts. He was also more independent, more a free lance, than his colleague, the editor of the *B M J*, who naturally and properly stood for the Association. He had the foresight and faculty of the literary critic and thinker. More than thirty years ago he published a compilation of papers, entitled "Medicine and the Public," which reveals the wide sweep of his comprehensive understanding of the new age, and embodies the views he had formulated in *The Lancet* before he became its editor in 1907. Though not widely read, it was an epoch making book and its remarkable prevision has been justified in the generation which followed. Sprigge understood, as few men, the principles of governance, what would be best yet what is only practicable, what would be good yet what could be got. He remained steadfast for the dignity of the profession and was jealous of its credit and repute. He did not suffer fools gladly and could be righteously angry. He was very keen on modern research from 1911 onwards, but was impatient when it appeared to go astray, no wild courses for him and no advertising. Wise and urbane man, happy and hopeful traveller, great editor, faithful friend—hail and farewell!

Sir William Collins.—As the biographer of the founder of *The Lancet* Sir Squire Sprigge seemed predestined to succeed the representative of the third generation of the Wakley family in the editorial chair of that journal. He brought to the office a scholarly mind and refined taste, qualities which imparted to *The Lancet* a distinction and independence which secured and retained the confidence and esteem of the profession. Among Sprigge's literary friends and co workers was Dr Sydney Coupland, whose wise and modest advice in medical journalism he gratefully acknowledged. Sprigge's own writings were characterised by width of view and liberality of sentiment. In his "Physic and Fiction" he asserts that "medicine is not yet an exact science," while repudiating the indictment of "a medical priesthood." He foresaw the need for unification of the public health and poor law services under a Ministry of Health and the supersession of the latter by the Local Government Board. If his advocacy of reforms and the redress of abuses was less dramatic and trenchant than that of the redoubtable Dr Tom Wakley, M.P. the first editor of *The Lancet*, it was none the less effective by reason of its erudition and cogency.

Miss R E Darbyshire—The nursing profession owe to Sir Squire Sprigge a lasting debt for his help and wise counsel. During the sittings of *The Lancet* Commission on Nursing Sir Squire gave much time

and thought to our problems and took so great a part in the work of the Commission that his name will be gratefully remembered by nurses. His work for the welfare of our profession will prove of increasing value to us all.

Sir William Rothenstein—I scarcely realised when I first knew Squire Spriggs that he was a medical scientific man. To me he was of the clan of writers and painters who met at Robbie Ross's rooms at the Café Royal at the Savile Club to discuss books and poets and the sins of the bourgeois. Spriggs seemed to know all about painters, *pro* Raphaelites and impressionists and joined in our worship of J. M. W. Whistler. To him also Meredith and Swinburne were god-like heroes; those were days when we were hero-worshippers as well as revolutionaries and scoffers. Spriggs had the painter's eye and the large humanity of the writer, a combination which gave an added grace to a naturally gracious mind. No one was quicker to detect talent in his contemporaries and to hearten the hopes of those who pursued wisdom and beauty in one way or another. And to our rougher, more impatient natures he held up a standard of courtesy and quiet wisdom which he retained during the course of his own life.

Mr Harold Barwell—On meeting Sir Squire Spriggs one recognised at once an uncommon personality. A small slight figure, his well-marked features evidence of his great strength of character were relieved by a humorous expression and his smile was charming. He was a modest man whose unaffected manner put everyone quickly at his ease. A good conversationalist, with a fund of anecdote, he was also a good listener and was therefore the most pleasant of companions. I must speak, too, of his devotion to duty, his loyalty to his old school at St. George's Hospital and his many kindnesses, as well as of his outstanding ability. He was, indeed, exemplary in conduct, courteous in manners, easy of address and steady and firm in principle as became a master of his craft and a great man. We can all spare him.

Prof M Greenwood—A few months ago Sir Squire and I were dining together and in our talk the name of an eminent man prone to an oratory we did not relish cropped up. The truth is, you know," said Spriggs, with a characteristic tightening of the lips, "X. Y. Z. is getting ga ga." I assented cordially and lost myself for a moment in trying to calculate whether X. Y. Z. was twenty or only fifteen years younger than Spriggs. Indeed it was very difficult to believe that he was not one's own age or younger and some newspapers will be unjustly suspected of publishing portraits of him taken at least a quarter of a century ago. Yet with this perennial youthfulness he combined a flavour of a past age. He was never the old gentleman shaking his head at modern follies; he often seemed a reincarnation of the spirit of the eighteenth century or rather of what we idealise as its spirit. With neither under-valuing nor over-valuing the little good things of life, with an unerring eye for humbug and an intellectual pleasure in a neat, clear argument, one felt he would have been on terms of happy equality with Charles Fox, William Windham and Dr George Fordyce.

Those who had the privilege of close association with him can speak with fuller knowledge; to me he seemed an ideal mentor for young men with literary ambitions. I grieve over the loss of a kind friend

but rejoice that to him was vouchsafed a portion we all should make:

Let me not live
After my flame lacks oil to be the scold
Of meaner spirits.

His flame never lacked oil

Mr Cecil Binney—To me Sir Squire Spriggs stands out as my first grown-up friend. As I had been some years at a public school when I first met him I had previously seen and talked to numerous grown-up people, but those who were not school masters were older relations or friends of my family who kind as they might be always treated me as a schoolboy. Dr Spriggs was entirely different. It was not only that he treated me as a grown person, he was himself at the same time so extraordinarily young. He entertained me and discussed current affairs with me as though I were a contemporary. I went with him to the South Kensington museums I had often been to them before but in his company they took on a different aspect. From being gloomy places where children were sent on Sunday afternoons they became galleries where educated people wandered around and discussed the exhibits without any pretence of taking them too seriously. It was like going with one of one's own friends who happened to be extremely well informed and entertaining. Yet there was no affected boyishness about him. His attitude to life was one of kindly tolerant cynicism as though he could understand and pardon everything. Before I met him I had heard a great deal about him and thought of him as a unique parent who did not mind his children or their friends wearing strange clothes or adopting strange creeds and had amused but kindly comments to make on any such developments. It had come therefore as a surprise to me to find that he lived like other people in a normal Kensington house with furniture. But that was my ignorance. I had not enough experience of the world to know that with his breadth of mind his comprehension and complete sincerity he could have no use for any eccentricity.

Mr John Paul Ross—To the younger generation the company of Squire was a great treat and joy and a visit to him was always happily anticipated and even more happily realised. His was a wit that made that of other reputed raconteurs seem laboured and the versatility of his mind was surprising. He seemed to have an inexhaustible fund of knowledge, and he would contribute to almost any subject of conversation in a way that was all the more authoritative because of its modesty and lack of dogmatism. His sympathy and kindness to all was a by-word but none had in him a greater partisan than young people. He had no use for those who constantly lament the efficiency of the present generation and we have lost a true champion. All will miss Squire Spriggs: the clubs whose smoking rooms he delighted the medical profession which he served and the countryside which he loved to paint, but none will miss him more than we youngsters.

Mr F. C. Goodall—As a beginner in a branch of journalism on the fringe of medicine I called at *The Lancet* office some thirty years ago to leave some copy in the hope that it might be used and I was told that the editor would see me. Having hitherto in my short acquaintance with him received more luck than halfpence I was prepared for another kick and resigned to the thought of it. But nothing like that happened. Going into the presence humble and perhaps scared I was at once put at my ease

and for the first time in my newly started career was made to feel a person of some use in the world. He gave me friendly advice and commissioned me to write an article on a subject he suggested, and when the interview was over he did not dismiss me with the nod to which I was accustomed, he walked down stairs with me and shook my hand at the street door. I went away with a new hope and a new heart and vowed that if ever it was my lot to become a leader of any concern I would show the same courtesy to young aspirants.

Dr C P Blacker.—The intense masculinity of his personality and the enormous range of his culture were capable, at first, of inspiring many people with feelings of respect amounting to awe but these were quickly thawed by his friendliness, his humour, and his directness. Very soon one found oneself talking to him as to a man of one's own age. The wide range of his friendships and of his experience of affairs frequently led to attempts being made by younger men to draw him out, to their asking his opinion about controversial matters or outstanding personalities. His power of giving humorous, penetrating yet always kindly appreciation of people and events was memorable. Good qualities never went unrecognised by him, but weaknesses rarely passed undetected. Nearly everyone, as described by him, was likeable, understandable, and human, and the world as seen by him was a better place, peopled by pleasanter people, than as seen by most. His personal modesty was one of the most obvious of his traits, but it did not take long to recognise, in the background of his personality, as an implication and corollary of all that he said and did, an integrity of mind and a fineness of personal quality which made it understandable that he was held in both affection and esteem by his juniors no less than by his contemporaries.

Mr Anthony Bevir.—First as a boy, and afterwards as I grew up, he always seemed to stand for courtesy and kindness in the world of affairs. I am quite sure (memory may be fallible but in this it should not be) that he gave me, each at its appropriate stage, the unexpected half sovereign, then the early cigar, or glass of port at his club, then a suitable range of introduction there, and finally (amongst other things) the suave covering of ignorance on library committees and so forth. I daresay he enjoyed watching the grub turning into a moth but the appreciation was not only on his side. And always there was an appropriate flow of worldly wisdom, touched and lightened by a delightful half mordant, half sympathetic wit.

The truth is, I think, that he liked young people and was naturally more at ease with them than with their elders in the world, though he moved easily enough among them. Adult humanity was not infrequently suspected of humbug, and if there was one thing he detested it was humbug, though he would be the first to appreciate its nicer uses. I think he might have said that it was probably less developed in the young.

It is not for me to write of his professional side either as physician or journalist, though I have had reason to be grateful for advice from his experience or knowledge of both spheres—I only write as a young friend, always engaged by his conversation, delighted in his books ("An Industrious Chevalier" read and re-read always with fresh pleasure) and grateful for his unvarying generosity and kindness. As I write this I inevitably think of his own judgment on what I have written. That young man, he might have

said, with a slight deprecation, might just as well have made it a sovereign while he was about it. Those who knew him will know what I mean.

AT THE MEMORIAL SERVICE

Lord Dawson said. At this service of remembrance I will try and give expression to our admiration and thankfulness for the life of Squire Sprigge.

The son of a Norfolk doctor, he belonged to the countryside, and there his spirit lived during life, and his body now rests. His life was long, rich and varied in achievement, clear and staunch in its purpose. Coming from Uppingham, Caius College, and St George's Hospital, his career was from the first that of author and journalist in varied fields, to which he brought scholarship, competency, and a lively sense of the problems of his day and generation.

The Lancet—this was the chief sphere of his work and influence. His association with that great journal began when he was aged thirty four, and he was editor, by succession from the distinguished Wakley family, for the last thirty years of his life. And picture those years—the rising tide of new knowledge, the growing concern for the health and weal of the people, the uprise of medical insurance and communal services—those and other changes surged round us in the hurry of the times. From Sprigge in his weekly chronicle came the still small voice of reason, which went far to save our profession from the mere clamour of the passing life. Let me bear witness to the service rendered not only to medical science but to national well being by those friendly rivals, the *Lancet* and the *British Medical Journal*, who both regard power as a trust for the public good. Together they embody the expression of the compass, the expanding sphere, and the dignity of English medicine of which the last two generations have been the witness.

With the passing of the years Sprigge's influence radiated far and wide. His culture and urbanity, his liberal outlook and quick appreciation, his enterprise of thought and youthfulness of spirit, and his apt choice of word and phrase made welcome his counsel and companionship. That his life was many-sided is shown by his devotion to sport in his youth, and in later life his enthusiasm as a painter in water colour and his love of gardens. For him beauty was truth and truth beauty.

He was a leader by the force of example, the power to persuade and encourage others and to make his workers feel themselves to be friends engaged in a common enterprise, and his kindness had a sureness of touch which brought all men to him. And yet he was a shy man who sought the shadows, forgetful of self though never forgetful of others. Without sense of mission, his message was part of himself, "for a man's soul is sometime wont to bring him tidings, more than seven watchmen that sit on high on a watch tower." All through he made truth and the counsel of his heart to stand.

His work done—we say farewell and hold fast to a memory—proud, grateful, and long abiding.

The following SPECIAL PRAYER was offered—

O THOU who knowest the secrets of men's sufferings and strivings, we heartily thank Thee for the long life of him whom we mourn to-day, and for his courage and steadfastness in the tasks that were committed to him. And we pray that all we who have known him and loved him, or have worked with him and for him, may likewise find out the way through all perplexities to serve Thine eternal purposes.

DISORDERS OF CONDUCT

Dr R. G. Gordon of Bath delivered the Morrison lectures before the Royal College of Physicians of Edinburgh last week. His subject was the neuro-psychological basis of conduct disorder the latter being defined as any behaviour not in accordance with the accepted code of the community in which the individual lives. To understand the neurological correlates of conduct one must study the neurological basis of emotional life and Dr Gordon emphasised the importance of the thalamic and hypothalamic regions in the control of emotions. These lower centres are under cortical control. The main afferent systems converge on the posterior part of the cerebral hemispheres where are situated also the mechanisms for visual and auditory imagery. In front of the central sulcus the brain tissue is largely effector in function and disease of the frontal region may lead to behaviour disturbance. In a series of 200 cases of conduct disorder in children there was no discoverable organic factor in 70 per cent. Even when there is an organic factor Dr Gordon holds that it merely loosens the control of an uncoordinated emotional activity. The study of cases of encephalitis and of chorea is of special interest for in these diseases there is evidence of destruction of cortical cells and consequent interference with control over the emotions.

The study of epilepsy also throws light on conduct disorders. The personality of the epileptic is peculiar. He is solitary, selfish and incapable of normal affects. He shows egotism, morbid sensitiveness and poverty of ideas; he adapts himself badly to social conditions. In some respects he is not dissimilar to persons who have been deprived of their prefrontal cortical areas. Such a person may have high intellectual capacities and yet a defective power of social adjustment. The extreme example of this was Napoleon. The lecturer suggested that the symptom of epilepsy depends on three factors: (1) a state of undue sensitivity or irritability; (2) the excessive number of cells receiving stimuli from the afferent division of the nervous system; and (3) an imperfect inhibition or control by higher levels in the nervous system. Conduct disorders if they occur in epilepsy are sudden, violent and unexpected. The conduct of mental defectives may be regarded as a too direct response of primitive behaviour patterns not far removed from instincts and there are as a consequence poorly developed powers of inhibition. Dr Gordon maintained that the great majority of those who commit a social act of conduct disorder are neither psychotic nor even psychoneurotic. The key of the situation is usually some obvious condition in the complex unity built up by the individual's relations with his environment. It is desirable therefore that in young children stimuli that are likely to evoke undesirable responses should be avoided. As the child grows older a system of ideals and internal inhibitions is built up which serve as a means of regulating conduct. If the instincts are unduly inhibited or unduly released it is not easy to build up a smooth social integration.

EXPERIMENTAL CEREBRAL DEGENERATION

At a meeting of the Edinburgh Pathological Club last week Dr David Orr gave the results of some experiments he had made on pregnant rabbits. He

found that by repeated injections of Atorol into the general circulation of the rabbit he was able to cause necrotic lesions in the fornix and cornu ammonis of the brain of the embryo. After similar experiments with acridine hydrocephalus was commonly produced and was associated with perivascular hypertrophy of neuroglia in the subventricular region.

CONGO RED FOR PULMONARY HÆMORRHAGE

Dr J. Popoviciu, senior physician at the Geogiu Sanatorium, has been giving the Bucharest Medical Society an account of his experiences in treating pulmonary hæmorrhage with Congo-red. He pointed out that all the methods in general use have some defect or other. Collapse therapy acts quickly, but it is not always applicable and the means are often not available while the doubtful value of various drugs, opiates, vasoconstrictors and coagulating and hypotensive substances is shown by the great number recommended. Of drugs put forward of late years Congo red has proved the most effective in his hands. It was introduced by Becker in 1930 and Morlock and Pincin recorded a long series of cases in which it failed only twice. In Rumania, Copaceanu and Letu described 11 cases of pulmonary hæmorrhage, with loss of at least 50 c.c.m. of blood in all of which Congo red gave very good results. Usually one injection sufficed to stop even large hæmorrhages.

The hæmostatic action of Congo red has been used for other purposes besides relief of hæmoptysis; thus it has been tried for the intestinal hæmorrhages of typhoid and for hæmophilia. Its exact action is unknown but experimentally it changes the clotting time, increases the number of monocytes, induces thrombocytosis, and augments the quantity of fibrin. According to recent observations it also stimulates erythropoiesis which explains the favourable results achieved by Massa and Zoles in pernicious anemia.

The method is very simple. The dose is 10 c.c.m. of a 1 per cent solution and it must be given intravenously. Sometimes the injection causes shivering for a short time caused by a cardio-depressive shock and in order to avoid this the dose has been decreased to 5 c.c.m. but the reduction also diminishes the hæmostatic action. Doses larger than 10 c.c.m. are not advisable though they are powerfully hæmostatic for they may cause a collapse that may even threaten life. If hæmoptysis recurs after the first injection the dose should be repeated after 4-6 hours. Dr Popoviciu administered Congo red in the Geogiu Sanatorium to 20 cases, and in 12 of them good results were achieved. The patients did not complain of any discomfort after the injections and Popoviciu thinks that intravenous Congo red injections should be regarded as an important antidote for pulmonary hæmorrhage.

TUBERCULOSIS MORTALITY IN RUMANIA

The tuberculous death rate in Rumania is one of the highest in Europe. It is higher in towns and cities than in the villages, and though it decreased in cities during 1932-35 it began to rise again in 1936. In general more men die than women and the age-groups most affected are those between 15 and 50. Mortality is highest in the early spring. In the mountainous districts of the Carpathians it is lower

than in the plains of the provinces of Transylvania and Bessarabia, excepting the mountains inhabited by the Moezs, where the disease is encouraged by poverty and by bad housing and food.

PROF MARINESCU'S RETIREMENT

Prof George Marinescu, who holds the chair of neurology and psychiatry at the University of Bucharest, some years ago reached the age at which professors are legally bound to retire. But at the request of the medical profession his retirement has been twice postponed. Now at 70 he remains full of vigour and it would be hard to replace him. The council of the University have therefore asked the Minister of Education to take steps, if necessary by Act of Parliament, to postpone Dr Marinescu's retirement yet a third time.

VIENNA

(FROM OUR OWN CORRESPONDENT)

MEDICAL CELEBRATIONS

THE last weeks of May gave a welcome opportunity to the medical profession to celebrate the centenary of our famous Gesellschaft der Aerzte in Wien (Medical Society of Vienna). All the progress achieved in the past century in medical knowledge in Vienna—indeed in Austria—has been reported to this learned body. Founded by Franz v Wirer, it soon attained such prominence in scientific circles that the imperial court delegated two arch-dukes to act as its patrons, while among its presidents we find the leading men of the profession. In 1893 the society opened its own house and it boasts of possessing the largest and best equipped medical library in Europe. In the 100 years of its existence over 4000 meetings have taken place. There have been over 15,000 demonstrations of patients and specimens and over 3000 papers have been read. We may mention among others Billroth's papers on the first total removal of the larynx and of the stomach, Koller's report on the use of cocaine in ophthalmology, and Freund's first demonstrations of the therapeutic use of X rays. The celebrations took the form of official receptions by the Government, by the city of Vienna and by the society, and a series of scientific meetings, in which representatives of foreign learned societies took part. There were also many informal social functions including some fine concerts.

Honorary degrees were conferred by the University on three veteran Viennese professors. Prof J v Wagner-Jauregg, Prof A v Eiselsberg, and Prof H Horst Meyer. In the issue of the *Wiener Klinische Wochenschrift* for May 22nd which is dedicated to the society the speeches at the graduation ceremony are reproduced. Over 600 medical men took part in the celebrations and there were also many official delegates from foreign societies.

It is of course impossible to mention all the lectures given at the scientific meetings and a short survey must suffice. Prof Paul Chairmont of Zurich (a former assistant in the Vienna clinic for surgery) gave an account of actinomycosis of the lungs, Prof August Mayer (Tübingen) spoke on the constitution in relation to gynaecology and obstetrics, Prof de Langen (Utrecht) discussed modern views on the circulation, Prof Walter Stoekel (Berlin) showed films of vaginal hysterectomy, Prof. Erich Lexer (Munich) lectured on infection of wounds, Dr

Verbelg (Budapest) read a paper on tumours, and Prof G A Wagner (Berlin) one on ovarian dysfunction and its treatment, Prof. R Leriche (Strasbourg) lectured on modern surgery to an enthusiastic audience, Prof Karl Wessely (Munich) spoke on myopia, Prof O Kahler (Freiburg) on the tonsils, and Prof J H Rille (Leipzig) on extragenital syphilis. Special meetings of the various medical societies were also held at which leading Viennese consultants, including Prof K. F. Wenckebach and Prof. Hans Eppinger, gave addresses.

TOO MANY DOCTORS IN VIENNA

In a communication to the Economic Society of Vienna Prof Eiselsberg reviewed the figures published by the dean of the medical faculty of the University and gave the following details—

Year	No. of students.	
	M	F
1912-13	2553	152
1913-14	2634	184
1919-20	3005	578
1936-37	2457	682

He also stated that last year in the present Austria of 6½ million inhabitants 58 more medical students graduated than in 1914 when the Austrian Empire comprised 36 million inhabitants. Fifty years ago Vienna had 774,000 inhabitants, with 1200 medical men. To day a population of 1,800,000 has 5300 doctors looking after its health. The proportion of one doctor for 645 of the population has gone down to one doctor for 340. Furthermore, the economic condition of the Viennese has deteriorated to such a degree that half the practising doctors can barely make both ends meet from their professional income, only one tenth have a paying practice, while the others do not earn enough to meet their daily expenditure. A substantial increase in the number of women practitioners (and specialists) also makes for over crowding with its harmful effects on the financial position of the profession, for competition is much keener and as a result fees are lower. Prof Eiselsberg thought an attempt should be made to restrict the number of students admitted to the medical faculty. He suggested that the preliminary examinations should be made stricter, and that the public should be informed of the large sums of money required to put a student through his medical course and set him up in practice. He referred to Sweden where only as many students are admitted to the medical register as are required to fill gaps in the profession caused by death or by the creation of new appointments. The system works there satisfactorily, but if it were adopted in Austria all graduation would have to cease for several years.

NEW HEALTH CENTRE AT LEEDS—Lady Swinton on June 11th opened a new health centre at Middleton. It is the first of its kind in Leeds.

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION—Post-graduate courses for July have been arranged as follows: in proctology at St Mark's Hospital (all-day, July 5th to 10th), in dermatology, at the Hospital for Diseases of the Skin Blackfriars (afternoons, July 12th to 24th), in urology at the All Saints' Hospital (afternoons July 12th to 31st), in general medicine and surgery, at the Miller General Hospital, Greenwich (July 10th and 11th). A special demonstration on the fundus oculi for M R C P candidates will be given on Tuesday July 6th, at 8.30 p.m. The courses are open only to members. Further information may be had from the secretary of the fellowship, 1 Wimpole street, London, W 1.

PARLIAMENTARY INTELLIGENCE

HEALTH ADMINISTRATION

IN the House of Commons on June 18th the discussion was resumed in Committee of Supply of the vote for the salaries and expenses of the Ministry of Health. It was agreed to have a general debate on health matters, including the work of the Board of Control.

Some Criticisms

Mr GREENWOOD referred to what he described as the melancholy history of housing during the past two years. The net result of ten years' operation of the Housing (Rural Workers) Act 1920 was to have pitched up about 12 000 rural cottages. So far as he could tell nothing had yet been done to deal with the problem of overcrowding under the 1935 Act. The reason he suspected was that local authorities realising that the Act was a fraud were concentrating their energies on the Act of 1930 where they had scope enough to keep them busy for some time.

MENTAL HOSPITALS

Mrs TATE asked whether the great sum of money being spent in mental hospitals was really necessary and whether its expenditure was touching the problem effectively. An enormous proportion of mental disease was of wholly physical origin which if it had proper treatment in the early stages would never lead to mental treatment being necessary at all. Almost nothing was done to treat mental disease in its early stages. She thought that Part II of the Board of Control's Report was one of the most unsatisfactory documents that had been published. In this report there was very little discrimination between the good hospitals and the bad, but the conditions in the bad could only be regarded as almost too appalling to be believed. Money spent on these was money poured down the drain. It was quite obvious that they must have more accommodation in many parts of the country. If they had to enlarge some of these hospitals could it not be done with far greater effect at very much smaller cost? Surely it was an experiment worth trying in one county to take some moderate-sized country houses, modernise them and put a certain class of mental patient there and have a panel of visiting doctors? The complaints were not so much of ill treatment as of the extraordinary lack of treatment and ghastly lack of understanding. Where that happened the fault was in the staff of the mental hospital. In many hospitals it was practically impossible to-day to get staff and the first improvement they ought to make in the bad hospitals was to improve the conditions under which the staff lived and worked. The whole country welcomed the fact that at St. George's they were attempting to undertake treatment of disease in the early stages but that should not be an isolated instance. It should be compulsory in every State hospital and should be urged on every voluntary hospital.

WALES

Mr JAMES GRIFFITHS appealed to the Minister to be far more generous to Wales in assisting her to develop her social services. Making out black lists of administrative counties in the three important and closely related matters of maternal mortality, tuberculosis mortality and overcrowding he found that there were seven Welsh counties on all three black lists—Anglesea, Denbigh, Carmarthens, Iembroke, Glamorgan, Monmouth and Cardiff. In those seven counties were 80 per cent of the total population of the principality. In the period from 1921 to 1933 maternal mortality in Wales exceeded the rate in England by 30 per cent while that in the special areas had been substantially increasing. Out of 13 administrative counties in South Wales eight had

no antenatal clinic yet they were among the counties that showed the worst maternal mortality rates. The average tuberculosis rate for the whole country during 1936 was 002 but every county and county borough except two in Wales was far in excess of that figure. Five administrative county boroughs having a rate well over 8000. The local authorities were too poor to spend more unless they were assisted.

EDUCATION OF THE PUBLIC

Captain ELLISTON congratulated the Minister of Health on the promised campaign to educate the people to use the health services already provided by local authorities in all parts of the country. He was grievously disappointed that the Minister had missed the opportunity of giving the House some assurance as to the promised long term legislation dealing with a national milk policy. There was a consensus of expert opinion that the case for the pasteurisation of milk was scientifically irrefutable and that by that means milk could be made as safe as water was made by chlorination and filtration. The real opposition to this protection was dictated by economic considerations. No doubt pasteurisation would involve producer-retailers in extra cost but if unfit houses and unsound food were prohibited was it reasonable that they should continue to allow the marketing of unsafe milk? The serious problem of rheumatism was receiving the attention of a great voluntary organisation, the Empire Rheumatic Council. If the Minister of Health could stand aside while voluntary bodies tackled problems of this kind then at least he ought to find sufficient funds for those bodies to get on with their work. They should also help by stimulating local authorities to do their part by establishing clinics which could be taken advantage of at a reasonable cost and also by providing wards and research units in poor law hospitals taken over by municipalities. Again the prospective decrease in our population was a problem that called for immediate recognition. It also had been handed to a voluntary organisation, the Population Investigation Committee which had no staff and no funds. He would have thought a matter of this urgent significance to the future of our race would call for the immediate appointment of a Royal Commission backed up by the resources of every Government department concerned. He also hoped that they would hear something from the Minister about the continued exploitation of the public by vendors of quack medicines and appliances. Practically all the facts were known and in the circumstances one could not but be surprised that an abuse of that kind should be allowed to continue.

Mr SANDERS said he did not understand how it was possible to conduct a progressive policy for the improvement of national health unless one had an estimate of human needs translated into terms of family income. He did not understand the apparent unwillingness of the Government to recognise the close connexion between spending power and adequate feeding. The Government should collect without further delay all the necessary information to enable them to lay down a minimum standard of life below which no one would be allowed to fall.

The Minister's Reply

Sir ROBERT WOOD, Minister of Health replying said that what was first needed in connexion with the problem of our declining population was research of a scientific kind, more facts, and a more satisfactory and informative method of getting population statistics. There were only two ways in which really complete information could be obtained—the census and the registration system. The latter was clearly the best for the purpose. Existing powers however only permitted of information relating to births to be

obtained for entry in the birth register, and full copies of this register could be obtained by the public. The objection to a proposal to enter up in it information about the date and duration of the marriage and the number of children previously born of the marriage would be met if it were arranged for the necessary particulars to be given to the registrar confidentially for statistical purposes only. Legislation for this would, of course, be required.

The treatment of venereal disease in this country was based on the recommendations of the Royal Commission that reported in 1910. The main feature of the scheme was the provision of centres throughout the country where full facilities for diagnosis and treatment were available free of charge to anyone who suspected that he might have contracted the disease. He would emphasise that the Royal Commission reported against any system of compulsory notification or treatment. They had built up on that system about 180 centres in England and Wales, and the total number of attendances by patients each year was well in excess of 3,000,000. In 1935 the total number of cases dealt with for the first time at the centres was 98,000, and of those as many as 30,230 were found not to be suffering from venereal disease. That showed that the centres were readily used by persons who were apprehensive of having contracted the disease and who were quite prepared to go there freely in the confidential circumstances he had mentioned. The policy and belief of the Ministry of Health at present was that the greater use of these centres could best be secured only by judicious education and propaganda on the importance of seeking early and skilled treatment. The anti-venereal disease measures in Scandinavian countries differed from ours essentially in having notification and compulsory treatment. A commission sent by the New York health authorities had recently issued a report which attributed an important part of the success in reducing the incidence of syphilis in Sweden and Denmark to notification and compulsory treatment. He did not intend to comment on that report. He had seen an important article in *The Lancet* which contravened a good many of the statements made in the report. He would leave it at that, but this report had attracted a good deal of attention and had, he thought, caused a revival, at any rate in certain quarters, of the agitation for compulsion here. In this country there had been a decline of 36 per cent in the figures of fresh syphilitic infections since 1931. It was true that between 1924 and 1929 there was apparently little or no decline, but since then the decline had been remarkable, and the rate of fresh infection with syphilis which was now in the region of 100 per 1,000,000 of the population compared rather favourably with the comparable figure of 220 per 1,000,000 in Denmark. A further special study of one or more of the Scandinavian systems might yield useful results, and the Secretary of State for Scotland and he were therefore arranging for one of the medical officers of his department who was particularly concerned with this matter and one of the medical officers from the Scottish Office, together with an administrative officer experienced in venereal diseases, to visit Scandinavia at an early date and report to them. That report should enable them to give further consideration to this problem.

MR. TURTON. Would my right hon. friend consider the extension of that inquiry to Holland where there is voluntary treatment? That would enable him to get both sides of the picture.

SIR KINGSLEY WOOD said he would certainly consider that suggestion. Continuing, he said that he recognised that a great deal more had to be done for housing and particularly rural housing. It was to be the subject of special study by the Central Housing Council, and he hoped that they would be able to do something further in rural areas. In regard to overcrowding he had made a number of inquiries from typical local authorities in the country as to the

exact position. Without putting into operation any of the penal provisions of the Overcrowding Act there had been a reduction in some of the ten or twelve districts with which they had communicated of some 20 per cent. That was rather interesting and pointed to what the position would be when the Act itself came into full operation.

HUMANISING MENTAL TREATMENT

He claimed for the mental health services that good progress was being made in the humane and progressive treatment of the mentally disordered and the mentally defective people of this country. Extracts had been given in the debate from the report of the Board of Control regarding a number of what might be called bad cases. Anyone who looked at that report would also see the records of a far greater number of good cases. He supposed that in no other country in the world would they see such a frank statement of the position in connexion with these mental institutions, and what ought to be done in the particular cases referred to. Directly the officers ascertained these cases they were placed on record, and the attention of the authorities concerned was drawn to the facts and they were called upon to do their best to remedy them. He would emphasise three things in connexion with the mental services of the country: there must be, first, constant vigilance in the conduct and control of these institutions, secondly, unabated efforts to secure the right type of nurse, and thirdly, vigorous investigation of any instances reported of ill usage or bad treatment. There was great scope for further research into the causes of mental affliction, and recently he appointed a committee under the chairmanship of Lord Radnor to see what further could be done to advance research. The need for providing further accommodation was fully realised. Many schemes were in hand and in contemplation which should overtake this. The total amount of loan sanctions last year for the purposes of the Lunacy and Mental Treatment Acts was over £2,000,000 as compared with £1,700,000 in 1935-36. One of the best signs of the time in connexion with the treatment of mental disease was that the flow of voluntary patients had steadily increased. Last year more than 25,000 patients were admitted to public mental hospitals and of these nearly 27 per cent were voluntary admissions. The number of out-patient clinics had now reached a total of 105. Mrs. Tate's suggestion about taking over country houses had been tried and had been found rather expensive, and not very practicable. He assured Mrs. Tate that the importance of physical illness as a causal factor in mental disorder was widely recognised. Within seven days of admission the medical superintendent was required to send to the Board of Control a medical statement of the mental and bodily health and condition of each patient.

They were taking steps in this country to build up a nutrition poller. He would like the committee to look at the report signed by all the leading men of the country including Sir John Orr, Prof. Cathcart, and Prof. Mellanby. Their recommendations he was carrying out at the present time and a number of inquiries were now in operation. In many directions the local authorities, owing to the increased sums of money available to them under the block grants, were now extending their services in connexion with milk for children and expectant mothers and matters of that kind. Owing to individual differences it would be quite impossible to lay down any standard of food requirements to be applied to all people alike. The best that could be done in present circumstances was to suggest standards in relation to man value in terms of energy requirements, the unit being on a sliding scale according to muscular activity. The other inquiries which the Advisory Committee recommended were now in progress. In conclusion, Sir KINGSLEY said that in the long and continuous fight—which had still to go on—against disease and ill health we were steadily gaining ground.

NOTES ON CURRENT TOPICS

The Factories Bill

On June 15th 10th and 17th in the House of Commons the Report stage of the Factories Bill, as amended in Standing Committee was concluded.

Mr SAMUEL HOARE, Home Secretary moved a new clause providing that adequate and suitable facilities for washing, including a sufficient supply of soap and clean towels should be provided in certain specified factories and that it should come into operation on July 1st 1939. After some debate Mr Samuel said he would withdraw it on the grounds that it was not comprehensive enough and have it drafted on different lines bringing it forward when the Bill reached the House of Lords.

Sir S. HOARE moved a new clause to ensure that suitable accommodation in all factories should be provided for clothing not worn during working hours and that suitable arrangements should be made for drying such clothing. The new clause was read a second time. An amendment moved by Mr MANDER to give the Home Secretary power to prescribe also a suitable standard of facilities for drying clothing as agreed to and the clause as amended was added to the Bill.

Mr LLOYD Under-Secretary Home Office moved a new clause providing that in any specified process that involved a special risk of injury to the eyes from particles or fragments thrown off in the course of the process, suitable goggles or effective screens should be provided. This clause was read a second time and added to the Bill.

A clause moved by Mr BANFIELD to prohibit night baking was negatived by 228 votes to 125 after debate. Mr ELIAS SMITH moved a new clause to provide safety first committees in factories; but this was negatived by 202 votes to 119. Lieut.-Colonel RANDIEMAN ALLEN moved an amendment to Clause 2 which deals with overcrowding to the effect that where a room contained a gallery a gallery should be treated as if it formed a separate room. This was agreed to. Mr RUDLEY moved an amendment providing that it should be the duty of an employer to post up a notice in the factory and workroom stating the number of employees who could be engaged there at one time within the terms of the Act. This also was agreed to.

On Clause 14 dealing with the fencing of other than transmission machinery Mr LLOYD moved an amendment, which was agreed to, providing that the Secretary of State might make regulations directing that when there was a really good safety device for any machine its use should be compulsory. Mr SMITH moved an amendment to Clause 52 (underground rooms) to the effect that no work should be carried on in any underground room unless the room was certified to be suitable on hygienic grounds and, in particular, as regarded construction, light ventilation and adequate means of escape in case of fire. It was negatived by 209 votes to 131. Mr LLOYD moved an amendment which was agreed to providing restrictions in regard to the use of underground rooms. He said that it represented a very considerable tightening up of the provisions in that respect.

Mr LLOYD moved a series of amendments to Clause 53 (basement bakehouses) providing for recertification or re-examination of basement bakehouses to see whether in the light of modern conditions they were suitable for use. This was agreed to.

On Clause 60 (General conditions as to the hours of employment of women and young persons) Mr R. J. DAVIES moved an amendment providing that it should not be lawful to employ in a factory a young person under the age of 15. He said the new machines and the speeded up machines in industry were becoming too dangerous for children to handle. Now that they were about to launch a campaign for greater physical fitness and to pass

this amendment would be a great contribution. Sir S. HOARE said the Government could not now repudiate the policy they had adopted in the last Education Act after the closest consideration and exclude from beneficial employment something like two-thirds of the young people whom they were now discussing and who were actually employed in factories and workshops. In a subsequent clause in the present Bill the Government were reducing the hours of work of these young persons by four hours a week and were prohibiting overtime for them altogether. He could give an assurance that cases of exemption would be very carefully considered and the employers would have to justify their demands for individual young persons. It would thus be quite impossible to change the considered policy of the Board of Education and instantly to bring about in industry unnecessary dislocation and in many cases harm to the young persons by driving them into unsuitable employment. After further debate the amendment was negatived by 207 votes to 137. Mr DONNIE moved an amendment to substitute 40 hours for 48 hours as a maximum working week for women and young persons. Sir S. HOARE said that this if carried would make a tremendous change in industrial life and would cause considerable dislocation. The amendment was negatived by 191 votes to 128. Mr LLOYD moved an amendment providing that the hour for stopping work should not be later than 8 o'clock in the evening in the case of young persons under 10 and 8 o'clock in other cases. This was agreed to.

On Clause 124 (Appointment and duties of examining surgeons) Mr R. J. DAVIES moved an amendment providing that subject to the consent of the employed person concerned the examining surgeon should have the right to inspect the medical records of the medical practitioner employed by the occupier of the factory. Mr LLOYD said the proposal would not be practicable. There was a serious objection to the suggestion that the examining surgeon should have the right to conduct a sort of roving inquiry into records of another practitioner irrespective of his precise duties under the Act. The Home Office thought it would be more practicable to leave the matter to be settled between the two doctors. The amendment was withdrawn after an assurance from Mr LLOYD that this point would be borne in mind in relation to the subsection under which the Home Secretary may regulate the duties of the examining surgeon. Mr I. SMITH moved an amendment providing that where any person was liable to contract an industrial disease from any process carried on in a factory the examining surgeon should examine such person at least once a month during working hours and keep a record for examination by the Inspector. Mr LLOYD said that the term industrial disease in the amendment was very vague and might include a large variety of diseases. A vast number of examinations would have to take place and it was too rigid a requirement to lay down a month as a period for examinations. It ought to depend on circumstances. Silicosis for example, developed very slowly and a highly technical and skilled diagnosis was required which the ordinary doctor was not capable of carrying out. In dermatitis the position was exactly the reverse. It developed very quickly indeed and a monthly examination would not be frequent enough. If the power which the Home Secretary possessed in Clause 11 to require the medical supervision of workers in all factories in certain circumstances was used as he was sure it would be it might prove a very important provision in industrial disease. The amendment was withdrawn.

Methylated Spirits (Scotland) Bill

In the House of Lords on June 16th the C stage of the Methylated Spirits (Scotland) Bill concluded.

On Clause 1 (Restrictions on sale of

spirits), Lord ASKWITH moved the following new subsection

"Nothing in the foregoing provisions of this section shall apply to surgical spirit sold by an authorised seller of poisons on registered premises or supplied by a duly qualified medical practitioner, registered dentist or registered veterinary surgeon for the purposes respectively specified in Subsection (1) of Section 19 of the Pharmacy and Poisons Act 1933, if the requirements of Subsections (2) and (3) of the said section are complied with in relation to such sale or supply of surgical spirit in like manner as if it were a medicine"

The amendment was agreed to. On Clause 6 (Interpretation), Lord ASKWITH moved an amendment providing that the expressions "authorised seller of poisons," "registered dentist," and "registered veterinary surgeon," should have the like meanings as in the Pharmacy and Poisons Act, 1933, and the expression "registered premises" should mean premises duly registered under Part I of that Act. This was also agreed to.

Young Persons and Health Insurance

In the House of Commons on June 22nd Sir KINGSLEY WOOD, Minister of Health, presented the National Health Insurance (Juvenile Contributors and Young Persons) Bill, a measure to amend the National Health Insurance Act, 1936, so as to make certain persons under the age of sixteen eligible for medical benefit, to facilitate the provision of medical benefit to such persons and to other young persons, and for purposes connected with the matters aforesaid.

The Bill was read a first time.

QUESTION TIME

WEDNESDAY, JUNE 16TH

Persons over 70 and Public Assistance

Mr LANSBURY asked the Minister of Health if he could inform the House how many persons over 70 years of age resident in the County of London were receiving grants from the public assistance authority owing to the insufficiency of the pension for their maintenance and the total yearly cost to the London rates of such payments, and if he would give the same information in regard to Manchester and Leeds and the counties of Glamorgan, Monmouth, and Durham.—Mr BERNAYS, Parliamentary Secretary to the Ministry of Health, replied: The returns made to my Department relating to persons in receipt of poor relief do not distinguish the number of such persons over 70 years of age. The returns do, however, show the number of persons over 65 years of age drawing old age pensions under the various Acts who are also in receipt of outdoor relief. I regret that information as to the amount of expenditure on poor relief to old age pensioners is not available in my department. The following is a table giving information as to the number of persons over 65 drawing old age pensions who are also in receipt of outdoor relief—

Administrative County of London	24,787
County Borough of Manchester	5,609
County Borough of Leeds	2,988
Administrative County of Glamorgan	8,476
Administrative County of Monmouth	3,477
Administrative County of Durham	8,015

International Red Cross and Spanish Refugees

Sir HENRY CROFT asked the Secretary of State for Foreign Affairs whether he was aware that General Franco offered that the old men, women and children of Bilbao should be evacuated to a zone west of Bilbao under guarantee from the International Red Cross, and that such zone would not be used for military purposes, whether this offer was conveyed to H.M. Government, and whether any steps were taken to provide such an asylum on Spanish soil under guarantee of the Red Cross before thousands of Spanish children were taken from their parents and removed to foreign countries.—Mr LORRY replied: A proposal to this effect was contained in the

reply received from the insurgent authorities to the communication made to them by H.M. Ambassador at Hendaye, in which notification was given of the steps which the Government proposed to take to protect Basque refugee ships. H.M. Ambassador accordingly inquired of the insurgent authorities whether their proposal constituted an offer of subsidiary action to that which was then being taken and whether it might be put before the Basque authorities with a view to the opening of negotiations. At the same time unofficial inquiries were made by H.M. Consul at Bilbao from whom it was, however, learnt that the Basque authorities did not regard the proposal as a practicable one, on the grounds that there were no villages between Bilbao and Santander capable of housing large numbers of persons, no water and no sanitary arrangements, and that the position of refugees might become untenable in the event of an insurgent advance in the direction of Santander. The insurgent authorities, as a result of the steps which had already been taken, subsequently made it clear that they were themselves no longer interested in the proposal, and it was, therefore, felt that no useful purpose would be served by pursuing it any further.

THURSDAY, JUNE 17TH

Persons Transferred from Poor-law to U.A.B.

Mr BATEY asked the Minister of Labour the number of unemployed who had been taken from the poor law by the Unemployment Assistance Board in Great Britain and also in the county of Durham, and the numbers refused up to the latest available date.—Mr LANCELOT BROWN replied: Information in respect of local government areas is not available but the following table shows, in respect of Great Britain and the Unemployment Assistance Board's administrative district of Durham, as on May 28th, in column (1) the number of persons in receipt of public assistance prior to the Second Appointed Day who had made applications for unemployment assistance allowances and who were taken over from public assistance authorities, and in column (2) the number of such applicants held to be outside the scope of the Unemployment Assistance Act.

	(1)	(2)
Great Britain	90,237	43,689
Durham district	2,775	1,404

Note.—Durham District includes the Board's administrative areas of Bishop Auckland, Chester le Street, Consett, Crook, Durham, Horden, Houghton le Spring, Pallion, Spennymoor and Sunderland (1) and (2).

Children Born in Prisons

Mr ROBERT MORRISON asked the Home Secretary what information was placed upon the birth certificates of babies born in prison with regard to their place of birth.—Sir S. HOARE replied: Governors have instructions that the word "prison" is not to appear in the notification to the Registrar, and that the name of the road or street in which the prison is situated is to be given as the address.

Mr WHITELEY asked the Home Secretary whether he was aware of the strong feeling against childbirth taking place in prison, and whether he was prepared to introduce legislation to abolish such practice.—Sir SAMUEL HOARE replied: This would involve an amendment of Section 17(6) of the Criminal Justice Administration Act, 1914, which gives the Secretary of State power to release temporarily a prisoner if he is suffering from disease which cannot properly be treated in prison or if he requires to undergo an operation which cannot properly be performed in prison. I will, of course, see that the question is not overlooked when any amendment of the Prison Acts and related legislation is under consideration, but I am not prepared to give any definite undertaking at the moment.

Ophthalmic Treatment in Schools

Mr DAX asked the President of the Board of Education how many children had been provided with spectacles in England and Wales under the arrangements made by the education authorities for the 12 months ended to the last convenient date, whether all local education authorities had the services of a qualified and experienced oculist, and at what periods were children's eyes

re-examined.—Mr KENNETH LINDSAY During the year 1936, 166,257 children attending public elementary schools in England and Wales were provided with spectacles under arrangements made by local education authorities. With the exception of the authority for the Isles of Scilly all local education authorities have arrangements for the treatment of defective vision by a qualified medical practitioner who has had special experience in ophthalmic work. All children in whom any defect of vision has been found are re-examined from time to time but the interval between the examinations depends on the nature and extent of the defect.

Official Tests of Gas Respirators

Mr PARKER asked the Home Secretary whether in view of his refusal to allow Members of Parliament to purchase Government gas respirators for carrying out experimental tests, he would now in the public interest publish the results of official tests which had been made.—Mr GEORGE LLOYD replied: The result of exhaustive official tests is that the civilian protector has been shown to protect effectively the face, eyes, and lungs against any type of gas which so far as is known, could be used in war.

Notification and Compulsory Treatment of Venereal Disease

Mr TURNER asked the Minister of Health whether in view of the conflict of opinion on the merits of notification and compulsory treatment of venereal disease and the remarkable reduction which had taken place in the incidence of syphilis in Scandinavian countries where this system prevailed, he would promote an inquiry to discover how much, if any of the Scandinavian success was attributable to this system.—Sir KINGSLEY WOOD replied: I am giving careful consideration to this matter.

Hospitals under Public Health Acts

Mr MERRICK asked the Minister of Health how many county and county borough councils had appropriated hospitals under the Public Health Act.—Sir KINGSLEY WOOD replied: Eleven county councils and 39 county borough councils in England and Wales have, since the Local Government Act 1929 came into operation, appropriated poor law hospitals or infirmaries or parts thereof, for use as general hospitals under the Public Health Acts. In addition, 6 other county councils have appropriated such institutions for other public health purposes, such as tuberculous hospitals, maternity hospitals, convalescent homes or epileptic homes.

Sanatorium Treatment of Tuberculosis

Mr MERRICK asked the Minister of Health if he could give comparative figures of cases of pulmonary tuberculosis treated in sanatoria under public health authorities for the years 1934, 1935, and 1936.—Sir KINGSLEY WOOD replied: The numbers of cases of pulmonary tuberculosis treated in public health and approved residential institutions during the years in question in England and Wales are as follows—

1934	30,850	1936	41,630
1935	40,484		

MONDAY, JUNE 21ST

Medical Examination of School-children

Mr LLOYD asked the Parliamentary Secretary to the Board of Education the number of school-children medically examined in the city of Leicester at the most recent convenient date; the number of medical examiners then employed; and the number of children then found to need medical treatment.—Mr KENNETH LINDSAY replied: During the year ended Dec. 31st 1936, 19,346 school children in the city of Leicester were examined at routine medical inspections, and 15,882 at special inspections. There were also 26,257 re-inspections.

The number of children found at routine medical inspections to require treatment for defects other than defects of nutrition, uncleanness, and dental diseases, was 1569. Information is not available to show the number of children found to require treatment at special inspections

but 11,277 defects requiring treatment were found. On Dec. 31st 1936 six whole time medical officers were employed by the local education authority in the work of medical inspection and treatment.

TUESDAY, JUNE 22ND

Children Injured by Spiked Railings

Mr MCGOVERY asked the Secretary of State for Scotland if his attention had been drawn to the large number of accidents in Glasgow where children had fallen on spiked railings; and whether he would introduce legislation to abolish all spiked railings on housing schemes.—Mr ELLIOT replied: The answer to the first part of the question is in the affirmative. Since 1922 the erection of spiked railings in or between back courts in Glasgow has been prohibited, and if a provisional order now before Parliament is confirmed existing spiked railings in or between back courts will become illegal after the expiry of four years from the date of confirmation.

Protective Equipment for Miners

Mr TOM SMITH asked the Secretary for Mines to what extent protective equipment in the way of helmets, gloves, &c. was in operation in the various coalfields.—Captain CROOKSHANK replied: The reports for 1936 of the Divisional Inspectors and of the Safety in Mines Research Board which will shortly be published contain a good deal of information showing that satisfactory progress has been made in the various coalfields in the use of protective equipment, hard hats for example being bought at a rate of more than 12,000 a month. I should like to take this opportunity of expressing my appreciation of the keenness and co-operation, shown by all sections of the industry, which have enabled a gratifying measure of progress to be attained.

Committee on Dangers of Celluloid Toys

Mr CARTLAND asked the Home Secretary whether he had yet set up the departmental committee to inquire into the question of the danger to children and others arising from the use of celluloid toys and other articles and if so what were its terms of reference.—Mr LLOYD, Under Secretary Home Office replied: I am glad to be able to announce that Sir Vivian Henderson formerly Parliamentary Under Secretary of State at the Home Office has consented to act as chairman of this committee and my right hon. friend hopes that the composition of the committee will soon be completed. Its terms of reference will be: To inquire into the use of celluloid to any similar highly inflammable material in the manufacture of toys, fancy goods, articles of attire, toilet requisites and the like and to consider what steps are desirable and practicable against the danger arising to the public and especially to children, from such use.

KING GEORGE HOSPITAL, ILFORD.—A festival dinner at which the Duke of Gloucester was the chief guest was held in aid of this hospital at the Mansion House, London on June 10th. The population of the immediate area served by the hospital has increased from 100,000 to 400,000 and the need for more accommodation is urgent. Over £6000 in donations was received at the dinner.

POST-GRADUATE COURSES IN BERLIN.—International post-graduate courses are to be held in Berlin on the following subjects: allergy in rheumatism (Oct. 4th-9th); natural methods of treatment (Oct. 11th-17th); tuberculosis (Oct. 18th-23rd); intrathoracic surgery (Oct. 25th-29th); infectious diseases in children (Oct. 18th-23rd); dermatology and venereal diseases (Oct. 18th-23rd); obstetrics and gynaecology (Oct. 24th-30th); homoeopathy (Oct. 11th-Nov. 6th). There will also be a course in diseases of the ear, nose and throat during October. Monthly courses in all the special departments of medical science including practical work are arranged. Particulars may be had from the information bureaux of the Kaiserin Friedrich Haus, Robert Koch Platz, Berlin N.W.

THE SERVICES

TERRITORIAL ARMY HOSPITALS

The War Office announces that it has been decided to form peace time cadres for Territorial Army general hospitals for home service on similar lines to those which existed before the late war. There will be 29 such hospital units and these will be distributed between the various military commands. The exact location of all of them has not yet been determined.

The serving personnel for each hospital unit will consist of 3 officers and 24 other ranks who will be members of the Royal Army Medical Corps, Territorial Army. The officers appointed will be the officer commanding, a registrar, and a quartermaster. The other ranks may be enlisted for home service only and the upper age limit for enlistment or re engagement will be 50. In addition, medical men will be appointed who will constitute the visiting and resident staff on embodiment, but who will not be required to do duty in time of peace.

It is intended that each hospital should be able to accommodate 600 patients (including 60 officers) in the first instance and be capable of expansion up to 2000 beds should the necessity arise. The following statement shows the peace and war establishments of officers —

PEACE ESTABLISHMENT

As stated above, the officers appointed in peace time will be a commanding officer (lieut colonel), a registrar (major, captain, or subaltern), and a quartermaster (non medical). The commanding officer will hold the rank of colonel on embodiment.

ESTABLISHMENT ON EMBODIMENT

(i) *The visiting civilian staff* (part time) will consist of 2 physicians, 4 surgeons, 1 ear, nose, and throat surgeon, 1 ophthalmic surgeon, and 1 anaesthetist.

(ii) *The resident staff* (whole time) will consist of 1 physician (major), 1 surgeon (major), 1 pathologist (major), 1 radiologist (major), 1 anaesthetist (captain), 4 general duties (captains or lieutenants), and 1 dental surgeon (captain or lieutenant). The four officers on general duties will be appointed after embodiment and will hold temporary commissions. All the other officers will hold T A commissions (Reserve of Officers) and will be appointed in peace time.

(iii) *Additional staff*—After embodiment 4 civilian medical practitioners (who may be final year medical students) will be appointed to part time employment or general duties.

The arrangements have been drawn up with a view to providing an adequate staff while interfering as little as possible with the medical care of the civil community. Proportionate increases in establishments will be authorised as hospitals expand, and hospitals for the treatment of special cases will have appropriate staffs selected accordingly. Part-time officers are to be not less than 50 years of age.

A further announcement will be made by the War Office when recruiting can begin. In the meantime application should not be made for enlistment into these units.

INDIAN MEDICAL SERVICE

ANNUAL DINNER

One hundred officers of the Indian Medical Service dined together on June 16th at the Trocadero, when Brevet Colonel Sir Rickard Christophers presided. The members of the Service present were as follows —

Major Generals W V Coppinger CIE, DSO, A W M Harvey CB, Sir Courtenay Mansfield, KCB, CMG, Sir John Megaw, KCIL, C W F Melville,

CB, Sir Leonard Rogers, KCSI, CIE, FRCS, Sir Cuthbert Sprawson, CIE, and G Tate, CIE.
Colonels H Answorth, J Anderson, CIE, Sir Charles Brierley, CIE, Sir Rickard Christophers, CIE, OBE, FRCS, H M Cruddas, CMG, OBL, H R Dutton, CIE, A B Fry, CB, DSO, C A Gill, T A Granger, CMG, C R M Green, W H Leonard, CB, H M Mackenzie, CIE, F P Mackie, CSI, OBE, Sir Richard Needham, CIE, DSO, J J Pratt, A H Proctor, DSO, C H Reinhold, MC, A Spitteler, OBE, Ashton Street, R G Turner, CMG, DSO, and W S Willmore.

Lieut Colonels J E Ansley, W P G Alpin, OBF, A C Anderson, C H N Baker, C H Barber, DSO, A C L Bilderbeck, R H Candy, CIE, H P Cook, D Clyde, D G Crawford, J M Crawford, OBL, J B Dalzell Hunter, OBE, S C Evans, J K S Fleming, CBE, P F Gow, DSO, V B Green, Armytage, A E Grisewood, J B Hanafin, CIE, J B Hance, OBE, W L Harnett, CIE, H Hingston, E H Vere Hodge, J M Holmes, E V Hugo, CMG, S P James, CMG, FRCS, M L C Irvine, I Davenport Jones, H C Keats, H H King, CIE, M M Khan, J B Lapsley, MC, J C H Leicester, CIE, C McIver, E C G Maddock, CIE, W A Mearns, F O N Mell, CIE, S H Middleton West, MC, F O'Kinealy, CIE, CVO, J Rodger, MC, OBE, H Ross, CIE, OBE, H K Rowntree, MC, J D Sambeif, J A Sinton, VC, OBE, R B Seymour Sewell, CIE, H B Steen, R Steen, W D H Stevenson, CIE, H Stott, OBE, W A Skes, DSO, H J H Symons, MC, C Thomson, G S Thomson, E Owen Thurston, A G Tresidder, CIE, E L Ward, CBE, and E L Waters.

Major H C Brown, CIE, J A W Edden, Sir T Carey Evans, MC, A Innes Cox, M J Quirke, and J Scott Riddle.

Captains T D Ahmad, H L Barker, and B V Rao.

Officers on probation B J Doran, J R Kerr, C F Mayo Smith, J D Munroe, G W Palmer, S Shono, W C Templeton, and G F J Thomas.

The last eight mentioned were present by invitation, and the other guests were Sir Frank Brown, CIE (the *Times*), Dr N G Horner (*British Medical Journal*), Maj General W P MacArthur, DSO, AMS, Sir Frederick Menzies, Dr Egbert Morland (*The Lancet*), Dr H Letheby Tidy, and Prof G Grey Turner.

SIR RICKARD CHRISTOPHERS in proposing the toast of the Service said that when a good many years ago certain new political changes were introduced into India, people used to think that the outlook for the Indian Medical Service was gloomy. Things had not worked out that way, looking round the room to night the Service seemed to him still going strong. Its history was long and, medically speaking, glorious. It had never been a service to provide merely medical attendance. Most of us, he said, have been organisers; many of us have brought special qualifications into the service. In the past the IMS had not only served the military and civil requirements of India, but had provided the botanists, the zoologists, and other scientific workers. All this had been put on record by the historian of the IMS, Col J M Crawford. It seemed to him that the activities of the IMS were none the less varied and important at the present time, witness the nature of appointments held by many of them after retirement, and in India there were still many whose names were well known in scientific circles. As to the future prospects, let me refer you, he said, to the new regulations just passed for the IMS, and it would

be innumerable if I did not say how much we as a Service owe to Sir Leonard Rogers Sir John Megaw and our present director-general for the way in which our case must have been presented to the authorities who decide these things. India offers splendid opportunities and a great variety of interests in life to those who go there. Probably only those who have experienced the life realise its fullness. I have been 30 years in the Service almost all my time in India, and never for one day have I been sick or sorry I joined nor have I seen any other service which could have given me the same pleasure and interest in life. We have heard a good deal about changed conditions but India is not the only place where there are changes and we cannot as a Service expect not to have to adapt ourselves to new things.

Lieut.-Colonel J A SEXTON V.C. who proposed the health of the chairman, described him as one who got at the basic principles of the subject he was investigating. At the tropical school they expected to get a whole-time worker and they only got some one who worked 12 hours a day.

After that Colonel Anderson told some stories and the dinner secretaries Sir Richard Needham and Sir T. Carey Evans received informal thanks.

INDIAN MEDICAL SERVICE

Col H. C. Buckley V.H.S. to be Maj. Gen. The undermentioned officers relinquish their temporary commissions. Capt. T. R. Pahwa M.A. Gaffar; M. Haftuddin, Copel Singh K. L. Malhotra K. V. R. Choudhary and Lt. A. Haq.

ROYAL NAVAL MEDICAL SERVICE

Surg. Capt. P. L. Gibson to Pembroke for R.N.B.
Surg. Lt. Comdr. (D) W. E. L. Brigham to Pembroke
Surg. Lt. C. J. Mullen to Pembroke

ARMY DENTAL CORPS

Capt. H. Quinlan to be Maj.

ARMY MEDICAL SERVICES

Lt.-Col. A. G. Biggam O.B.E. M.D. Edin. F.R.C.P. Lond., R.A.M.C. has been appointed Honorary Physician to the King (and promoted to the rank of brevet-colonel) in succession to Col. J. Healy Spencer O.B.E. whose retirement was announced in THE LANCET last week.

ROYAL ARMY MEDICAL CORPS

MILITARY

Maj. S. R. Armstrong O.B.E. relinquishes his command and retains the rank of Maj.

TERRITORIAL ARMY

Capt. G. L. Pillans M.C. resigns his command and retains his rank.

Lt. W. Bruce, from 6th Bn. Gordons to be Capt.
T. G. Armstrong (late Cadet Felsted Sch. Contingent Div. O.T.C.) to be Lt.

ROYAL AIR FORCE

Flight Lts. W. G. S. Roberts to R.A.F. Station, Dhillban, Iraq; H. E. Bellinger to R.A.F. General Hospital, Iraq; Hinaldi W. J. L. Dean to No. 84 (Bomber) Squadron, Shaibah, Iraq; and G. H. J. Williams to No. 6 Flying Training School, Netheravon.

PUBLIC HEALTH

Domiciliary Service of Midwives in London

On Tuesday the London County Council approved proposals to be submitted to the Minister of Health under the Midwives Act 1936. The Act makes the L.C.C. responsible for providing an adequate service of competent whole-time midwives for a domiciliary service (including maternity nursing). In so doing the Council must have regard to any existing provision made by voluntary or other agencies. These include a large number of voluntary hospitals with medical schools attached to them, voluntary maternity hospitals, and voluntary nursing associations while a certain number of London boroughs have either appointed whole-time salaried midwives or contribute to voluntary bodies engaged in domiciliary midwifery work. Having made suitable arrangements with these voluntary agencies and the borough councils the L.C.C. must supplement their services where necessary by appointing whole-time midwives of its own. With a view to efficiency London has been divided into five areas in each of which provision has been made.

(a) To the fullest possible extent for the existing voluntary agencies.

(b) For those boroughs which already employ whole-time salaried midwives.

(c) For supplementing the existing domiciliary midwives by the addition of a certain number of whole-time salaried midwives to be appointed by the L.C.C.

(d) For linking up the facilities provided by every Metropolitan borough in connexion with the Maternity and Child Welfare Act 1918.

(e) For the provision of hospital accommodation, both municipal and voluntary to whatever extent is necessary.

(f) For the application of a uniform scheme for the payment and collection of contributions by patients in accordance with the scheme.

(g) For the provision of a panel of medical practitioners, to be approved by the L.C.C. who will undertake to be called when required by the patient in their own home.

(h) For the provision of free choice of midwife to the fullest extent possible; and

(i) For the provision of reliefs for holiday duty, sickness duty and for emergencies, wherever and whenever required.

It is proposed that 42 midwives shall be employed directly by the Council and when the arrangements are complete every London mother irrespective of her financial circumstances will be able to call on the service of a fully qualified midwife and will have a choice of midwife. The fees proposed for the attendance of midwives are £2 for first confinements, £1 10s for subsequent confinements, and £1 10s for maternity nursing. Reduced fees will however be charged where the patient or liable relatives are unable to pay the full fees or the whole fee may be remitted.

In a separate report to the Council the hospitals and medical services committee refer to the recovery from patients or liable relatives of fees paid to medical practitioners called in by midwives in emergency and recommend that when the new scheme is brought into operation no charge should be made in respect of the doctor's fees in these cases.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
JUNE 12TH 1937

Notifications.—The following cases of infectious disease were notified during the week: Small pox 0; scarlet fever 1847; diphtheria 877; enteric fever 10; pneumonia (primary or influenzal) 607; puerperal fever 37; puerperal pyrexia 123; cerebro-spinal fever 26; acute poliomyelitis 8; acute poliomyelitis 1; encephalitis lethargica 4; dysentery 73; ophthalmia neonatorum 10. No case of cholera, plague or typhus fever was notified during the week.

FINAL EXAMINATION FOR L.D.S.

M G Davies J B Inverdale P H S Paine H W Williams, and J G Windmill

Epsom College

The eighty fourth annual general meeting of the governors was held at 49, Bedford square, W.C., on June 18th, 1937, with Lord Leverhulme, the president, in the chair. The results of the last election of a pensioner five foundation scholars, and an annuitant were announced. Lord Leverhulme then referred to the continued increase in the number of boys, and said that in 1936 the average number was 446, of whom 93 were day boys. He also referred to the royal patronage which His Majesty King George VI had graciously consented to extend to the college. The school had attained a fine record in scholarship work—no less than five open scholarships having been secured, one of the boys had won the public school quarter mile at the White City, and one master had gained his rugby cap for England. He drew special attention to the paragraphs in the annual report dealing with tax free subscriptions to charities. He pointed out that if all

the governors would sign the deed of agreement it would mean an increase of from £1500 to £2000 a year for the funds of the Royal Medical Foundation at no cost whatever to the subscriber

The following ten members of the council were re-elected for a further period of three years: Dr J W Carr, Dr Ronald Cove Smith, Mr F S Fleuret, Sir William Hale White, Mrs Robert Hutchinson, Dr Reginald Langdon Down, Dr Arnold Lyndon, Dr Philip Manson Bahr, Mr Arthur Ormond, F.R.C.S., and Mr Julian Taylor, F.R.C.S. Prof John Nixon, and Dr Henry Robinson were elected vice presidents of the college. Colonel Norman C King, Mr H H Rew, and Mr H A Decker were appointed auditors for the ensuing year. The chairman of the college proposed a hearty vote of thanks to all honorary local secretaries, the British Medical Association, the Medical Insurance Agency, the charities committee of the British Medical Association, numerous panel committees, and the editors of the *British Medical Journal* and *The Lancet* for all the work that they had done on behalf of the Foundation.

London and Counties Medical Protection Society

The annual general meeting of the society was held on June 16th at Victory House, Leicester square, W.C., with Sir Cuthbert Wallace, the president, in the chair. The chairman, in proposing the adoption of the annual report, first referred to the death of Dr R L Guthrie. Anyone who worked with Guthrie, he said, was at once attracted to the man, and the society owed him a great debt of gratitude for the work he did as treasurer, in the face of great physical disability. At the chairman's suggestion those present stood in silence as a tribute to Dr Guthrie's memory. Sir Cuthbert continuing, said the society was prospering, for during the past year they had elected well over 1000 new members, the membership standing at over 15,000. The applications for advice and assistance from members received during the year numbered over 1500, and the solicitors had to deal with nearly 800 cases. He thought it was remarkable that there must be still very many members of the medical and dental professions who remain unprotected. During the year they had admitted to membership certain of the dentists who came in under the Act of 1921, which he thought was a very wise proceeding. Having listened to the proceedings in the council and its committees one of the things that had struck him, he said, was the complexity of the modern operation. "As far as I know, legally the surgeon is still responsible for everything that happens at an operation but obviously that position cannot continue indefinitely through the years to come. The responsibility of the anaesthetist with his complicated apparatus and the responsibility of the nurses will have to be recognised in future. The surgeon can no longer go on bearing all the risks involved." The giving of a true certificate might require a great deal of moral courage and to get the true history out of a patient was one of the most difficult things on earth. Nevertheless, he urged those in general practice for their own protection to make correct notes and fill up the patients' cards properly.

Reverting to the happenings of the year he said the society had most wisely made provision for protecting members who had retired. Possibly the most important thing in the whole year was an alteration in the articles of association so that they were able to protect the estate of a deceased practitioner. The wisdom of that decision was shown in a recent action in which for the first time the estate of a deceased doctor was sued, with the final result that £5,000 damages was awarded, the society was able to help the widow to that extent. Finally, Sir Cuthbert said that silence was indeed the golden rule, especially when it is a question of the conduct of a neighbouring practitioner or a colleague in the same town. He urged those who got into trouble to consult the society at once and not to meddle with matters themselves before taking its advice.

Mr W W Mollison spoke on the financial side of the report. For the first time in recent years the balance sheet shows a deficit of £246, largely due to the heavy

(Continued from previous page)

The number of cases in the Infectious Hospitals of the London County Council on June 18th was 2851 which included: Scarlet fever 716, diphtheria 805, measles 116, whooping cough 456, puerperal fever 10 mothers (plus 10 babies), encephalitis lethargica, 282, poliomyelitis, 3. At St Margaret's Hospital there were 25 babies (plus 14 mothers) with ophthalmia neonatorum.

Deaths.—In 123 great towns, including London, there was no death from small-pox, 2 (0) from enteric fever, 0 (0) from measles, 0 (0) from scarlet fever, 17 (3) from whooping cough, 24 (1) from diphtheria, 31 (6) from diarrhoea and enteritis under two years, and 16 (3) from influenza. The figures in parentheses are those for London itself.

Four fatal cases of measles were reported from Birmingham 2 from Leeds. There were 3 deaths from diphtheria at Liverpool and at Wigan.

The number of stillbirths notified during the week was 281 (corresponding to a rate of 38 per 1000 total) including 43 in London.

expenses in the case which the president had mentioned in an analysis of costs per member most of them were an exception for the considerable item of adverse costs and damages which was increased by no less than 7s 7d compared with 1935. The total cost per member worked out at 11s 6d 7d so that they were apparently spending more per member than they received. The difference between the 11s 6d 7d spent and the 11 received, however, was accounted for by interest on investments and accumulated balances. A brochure was to be sent to all members of the profession not members of the society which would show in a more or less readable form the advantages of belonging to a protection society.

Sir Cuthbert Wallace was re-elected president and Dr M. Fegan secretary of the society. Dr Marguerite Kettle was elected to the council.

Mayoian Fellowship

The Association of Surgeons of Great Britain and Ireland invite applications for this fellowship which may be held for one year and is worth £350. Further information will be found in our advertisement columns.

An Ophthalmic Group

A meeting of ophthalmic surgeons and ophthalmic medical practitioners will be held at 3 p.m. on Saturday July 3rd at 17 Russell-square London W.C.1 with the object of constituting a group to protect their status and interests, especially in relation to unqualified prescribing and non-prescribing opticians, and to be organised within or with the approval of the British Medical Association.

Industrial Course

A short intensive course in industrial physiology and industrial psychology will be held at the London School of Hygiene, Keppel-street W.C. from Feb. 18th to 19th. It is designed for members of supervisory staffs in industry but it may also be of interest to industrial medical officers. It will deal with the general principles of industrial health and specific problems arising in industry. Further information may be had from the secretary of the school.

Millbrook Isolation Hospital

A tuberculosis pavilion of 44 beds was opened at the Isolation Hospital Millbrook Southampton on June 10th by Sir Arthur MacNalty. The new building raises the number of tuberculosis hospital cases and the health department can deal with at one time to 140. After the ceremony Sir Arthur said that the town's tuberculosis service was making steady progress and the medical officers' last annual report showed that the mortality-rate from pulmonary tuberculosis was the lowest ever recorded for the borough. It was still however above the average rate for England and Wales. One reason for that was that the town was a seaport and a high proportion of seamen suffered from tuberculosis that had been contracted elsewhere. He was glad to know that in Southampton co-operation between the medical practitioners and the tuberculosis services of the council was extending as was shown by the increase in the calls made upon the tuberculosis officer for consultation.

Order of St John of Jerusalem

The following promotions in and appointments to the venerable Order of the Hospital of St John of Jerusalem have been sanctioned by the King—

As Knight—Nigel Corbet Fletcher M.B. Lt.-Col. Sir James Earl Ennis, M.D. and Gregory Smyth M.D. C.I.E. O.D.E. R.C.S. I.M.S., Arthur Herbert T. Cardew M.C. M.B. F.R.C.S. (M.D. Honnall M.B. Thomas Herbert Goldard M.B. Henry Lindo Ferguson C.M.G. M.D. Eldon Pratt M.D. William Philip Stephens Ward, M.R.C.S. Major Edmund Hamilton Harrison T.D. M.R.C.S. Ernest McIntyre, M.R.C.S. Capt. Alexander Campbell White Knox, M.D. M.B. Charles George M.B. Major John Reith Thomas, M.B. William James M.B. Lt.-Col. Walter Rodney Hatley, M.B. F.R.C.S. As Officer—Major Alfred T. Cresswell-Smith, M.D. Clive Hamilton M.D. M.B. Col. William Brooke Purdon D.S.O. M.B. R.A.M.C. Michael Herbert Watt C.B.E. M.D. Lord Alton of Liverpool M.D. John Blain Thomas, M.D. Col. Frederick Hugh Maguire, M.D. D.S.O. M.D. Paul Lewis M.D. Henry Gill, L.R.C.I. and S. James Ansell Durante, M.D. John Willford Cooper, L.S.A. Capt. Sydney Booth M.B. R.C.S. Col. Philip Henry Mithribhai T.D. M.B. Major Ernest Cameron Wilson M.D. and Sydney Walter M.D.

Middlesex Hospital

The annual dinner of this hospital will be held on Oct. 1st at the Savoy Hotel when Dr Douglas MacAlpine will be in the chair. A refresher course for former students will also be held from Oct. 1st to 3rd.

London Hospital

On Tuesday July 6th at 3 p.m. Sir Kingsley Wood will distribute the prizes to the students at this hospital.

Royal Medical Psychological Association

The annual general meeting of this association will be held at the County Buildings, Ayr on July 7th 8th and 9th under the presidency of Dr Douglas MacRae who will give an inaugural address on the care of the insane. Dr A. Meyer Prof F. L. Golla Dr F. A. Pickworth and Dr A. C. P. Campbell will take part in a symposium on the circulatory system and the psychoses on the second day of the meeting. The last day will be devoted to a discussion of the symptomatology of vascular diseases in the psychoses and mental deficiency. Papers will be read by Dr W. Mayer Gross Dr E. Guttmann Dr A. M. Wylie Dr E. Krapf and Dr I. Macdonald. Dr K. Paddle will also speak on the prophylaxis of dysentery in mental defectives. Further information may be had from Dr W. Gordon Macfield the hon. general secretary, Brentwood Mental Hospital, Essex.

Health Congress at Birmingham

The Royal Sanitary Institute will hold its health congress at Birmingham from July 12th to 17th under the presidency of the Earl of Dudley. The work of the congress is divided into eight sections (preventive medicine engineering architecture and town planning maternity child welfare and school hygiene; veterinary hygiene; national health insurance hygiene in industry tropical hygiene and sewage disposal). There will also be conferences of representatives of local authorities medical officers of health engineers, and surveyors sanitary inspectors and health visitors. As president of the section of preventive medicine Sir Arthur MacNalty will give an address, entitled a Coronation Pageant of the Public Health and Prof J. M. Munro Kerr Dr G. F. Buchan and Dr C. F. S. Flemming will open a discussion on the development of the maternity service. Dr Ernest Ward will preside over the conference of the medical officers of health and Dr P. L. McKinlay Prof R. M. F. Picken and Dr E. R. C. Walker will take part in a symposium on incapacitating sickness. Dr G. P. Crowden will read a paper on the practical application of physiology to hygiene in industry to that section and Dr James Fenton will address the conference of health visitors on the training of the health visitor. A health exhibition has been arranged in connexion with the congress. Further information may be had from the secretary of the institute 90 Buckingham Palace-road London S.W.1.

Appointments

GRUNDY, FRED M.D. Leeds D.P.H. Medical Officer of Health for Luton.

LANIER, F. P. L. M.D., M.R.C.P. Lond. Hon. Assistant Physician to the Royal Free Hospital.

McDONOUGH, JOHN M.B. Glasg., M.R.C.P. Edin., Medical Superintendent of the Perth District Asylum, Perth.

MAYER, G. S. M.B. Camb. F.R.C.S. Eng., Surgical Registrar at the Southend-on-Sea General Hospital.

THOMAS, A. R., B.Sc. Camb., D.M. R.E. Hon. Radiologist to the French Hospital, London.

WALLACE, E. J. G. M.B. Edin., D.P.H., Medical Officer of Health for Weymouth and Melcombe Regis.

COUNCIL OF MIDDLESSEX.—The following appointments have been made—

PONTING, FLEAYSON G., M.R.O.S. Eng. D.P.H. Assistant Medical Officer.

STREETER, LEWIS S. M.B. Glasg., D.P.H. Assistant Medical Officer and

MATTHEWS, O. B., M.R.C.S. Eng. Assistant Medical Officer.

St Thomas's Hospital.—The following appointments are announced—

HENSTON, M. A., M.B. Camb. L.D.S. Assistant Dental Surgeon.

CHITTERTON, W. J., M.B. Liverp., Chemical Pathologist and

KLIN, J. P. M.B. Camb., Assistant Pathologist.

Certifying Paragon under the Factory and Workshop Acts Dr H. FALLOWS (Redcar District, Yorkshire North Riding) and Dr J. C. BRYNE (Lewer District, Wiltshire).

NOTES, COMMENTS AND ABSTRACTS

HISTORY OF NITROUS OXIDE AND ETHER

from from the *Evening Standard* of June 17th patient in an hospital at Baltimore, Maryland, died by an explosion in his lungs during an operation for a carbuncle on his neck. The account states: "The anæsthetic, a form of gas, had just been administered when there was an explosion which immediately killed instantly. Two nurses at the operation received slight injuries from the electric cautery machine which was being used at the time. The operation is thought to have caused the explosion. The operating surgeon who escaped unscathed afterwards: The gases in anæsthetic are oxygen, nitrous oxide and ether are not explosive. We use them in conjunction every thousands of times a year. It was just these unexplainable accidents that happen." The issue of March 6th last (p. 578) we recalled that Prof H B Dixon drew special attention to the recognised explosibility of mixtures in which nitrous oxide is replaced by nitrous oxide in conjunction with ether or other inflammable gases and also to the work of Mr J H Coste and Dr C A Blandy undertaken for the London County Council and published in the *British Journal of Anaesthesia* in which they say: "Nitrous oxide is endothermic and it has been found that when detonated it decomposes with violence into nitrogen and oxygen. The experiment illustrates the danger of diathermy. This conclusion was confirmed after experiments in which a mixture of 75 per cent. of ether shattered the explosion vessel. They also obtained a shattering explosion of ether and oxygen from a Boyle's apparatus. It is probable that the heat liberated on thermal decomposition of the nitrous oxide adds greatly to the violence of the other explosion. These facts cannot be unknown to surgeons."

THE HISTORY OF CONTRACEPTION

Mr Himes has devoted himself for the last decade to a study of the historical aspects and social aspects of contraception. The subject matter of his articles and papers has now been brought into a series of volumes which if we may judge from the first can justly be described as encyclopaedic. They are told by Sir Humphry Rolleston who writes a preface that this volume is to be followed by two others which will deal respectively with the social and economic aspects of contraception and with the relation of birth control to the fundamental aspects of modern population. These aspects of the question are actually dealt with by Mr Himes in no cursory spirit in the first volume concluding part of the volume under the title "The five preceding parts thoroughly fulfil the expectations raised by the title. The first deals with contraceptive technique before the dawn of history and is based on the reports of social historians. The second with the methods of birth control in the period of antiquity of the Western world; the third describes the practices of birth control in the ancient world; the fourth, the practices of birth control in the Middle Ages and early modern times; the fifth, the history of birth control in the United States and in the sixteenth century; and the sixth, the history of birth control in the United States and in the sixteenth century. The author sets out what he believes to be the history of the process of demoralisation which has brought about by a knowledge of chemistry and biology, and by the vulcanisation of rubber, the history of birth control. Mr Himes has drawn attention to

those writers whose prescriptions have a scientific basis of common sense rather than of superstition and magic; and the first of these writers in merit is deemed to be Soranos to whom the book is dedicated. Soranos pointed out that soft wool introduced into the mouth of the womb before coitus reduced the chances of conception and he named several astringent substances which would probably exert a spermicidal effect. Contrast the recommendations of Soranos with the following prescription of an Islamic writer: "If a woman urinates on the urine of a wolf she will never be with child; and with the intravaginal use of Casanova of gold balls for which he paid about 27 apiece."

The work is illustrated by reproductions of original Islamic texts, facsimiles of Francis Place's celebrated contraceptive handbills and in the later chapters by numerous figures, tables and charts. It is not a book to read from cover to cover but as a work of reference it occupies a unique place in medico-social literature.

SPURIOUS CHLORODYNE

A PRACTICE which is said to be spreading in the North of England especially in the industrial areas is the sale of substitutes for chlorodyne (tincture of chloroform and morphine) which differ in important respects from that compounded from the recognised formula. Since the genuine preparation contains morphine hydrochloride it can only be sold by registered pharmacists but the substitutes may be sold by any shopkeeper or at a stall in the market place. The sale of the spurious article as chlorodyne or chlorodyne substitute is to be strongly deprecated for more reasons than one, but the most important reason is the danger which the practice entails. The purchaser of the morphine-free product may take large doses of it without doing himself damage but being unaware that a subsequent supply of the medicine which he buys at a pharmacy is an entirely different and a potent preparation he will not know that it is unsafe to take the same large dose from the new bottle as he took from the old one. The risk is one that the purchaser should know how to avoid and if substitutes for chlorodyne are to be sold they should be sold under an entirely different name. It is an offence under the Food and Drugs (Adulteration) Act for a shopkeeper to sell to a person requiring true chlorodyne an article which is not true chlorodyne and it may be that the appropriate authority will take action to check the practice.

A POCKET VALVE AMPLIFIER HEARING AID

The Multitone Electric Company of 92 New Cavendish-street W 1 have produced a valve-amplifier hearing aid which can be worn on the person with comfort and efficiency and which obviates the necessity of carrying a case of the size of a small box camera. The new model the V.P.M. or Vest Pocket Multitone achieves this result by separating the various components, which are carried in different pockets and has the advantage that the receiver may be placed in the best position for collecting sound. Once the components are bestowed the apparatus is invisible except for the head phones, but it may be assembled in a case or in a lady's handbag if preferred. The apparatus comprises a crystal microphone to be clipped to the coat or waistcoat; a three-valve amplifier which is small enough to fit easily into a waistcoat pocket and which should be placed in some such accessible position for it incorporates the switch and the volume control; a 37½ volt high tension battery in a thin morocco case and of a flexible type for more comfortable wearing; and a 6-volt low tension dry battery. There is no variable tone control but models with different tonal responses are available to suit various forms of deafness and individuals

are tested by audiometer and amplification meter before the instrument is supplied. The Multitone "unmasked hearing" telephones are used, a method which employs two headphones in one of which intended for use in the better ear, the lower tones are completely eliminated, it is claimed that this gives better definition of speech, and that the absence of the masking effect of low tones results in gradual improvement of the hearing. The price of the instrument, including the double headphones as well as a small single earpiece for occasions when as inconspicuous an aid as possible is desired, is eighteen guineas, the high-tension battery may be expected to last for two to three months and costs 5s 6d, the low-tension batteries last about a week and cost 1s, or a battery of twice this capacity can be obtained for 1s 3d by those who do not mind the extra weight. The makers very properly allow a trial hire for seven days at a charge of 10s 6d. Since valve-aids undoubtedly give a far better and less distorted amplification of sound than other types of electric amplifier, a model which can be worn on the person will supply a want, and the instrument here described is efficient and well made.

THE FUTURE OF SEX RELATIONSHIPS

IN the future, according to Mr de Pomerai,¹ sex relationships will be purged of the elements of jealousy and of clumsiness by which they are stultified to-day. Extra-marital relationships will be permitted, but they must not detract from the affection, companionship, and financial benefits which should be enjoyed by the legitimate partner, and they will take their place in a psychological, social, and philosophical adjustment which we shall learn by following the Aristotelian principle of the Golden Mean and by adopting a pantheistic attitude to the ultimate problems of life. This formulation does not appear to be the product of a first hand experience of the sexual problems of others such as might be gained by a physician, it seems rather to have been evolved from reading the works of modern popularisers of science. The names of Wells, Huxley, Jeans, Russell, and Joad appear with a chilling frequency and the reader is finally presented, on the last page, with a picture which some will find agreeable of a Utopia which the author believes will be realised—but long after his own lifetime.

AGRANULOCYTOSIS AND AMIDOPYRINE

It appears that the risk of producing agranulocytosis by giving amidopyrine is still insufficiently appreciated. Writing in the *Nederlandsch Tijdschrift voor Geneeskunde* (1937, 81, 2328), E. Gorter describes a case in which a boy, five years old, was admitted to hospital in October, 1936, with profound anaemia, fever, and enlargement of the spleen.

He had previously had a long series of illnesses, acute otitis media a year before had been followed by recurrent attacks of bronchitis, lymphadenitis, and an undiagnosed infection clinically resembling osteomyelitis. At the beginning of the year during July, and again during September, amidopyrine had been given by the family doctor. A blood examination showed a hæmoglobin content of 33, erythrocytes 1½ millions, and leucocytes 150 per c mm. The differential white-cell count showed 50 per cent of lymphocytes. A blood transfusion of 200 c cm was given and a course of Pentnucleotide begun. A second blood examination, four days later showed hæmoglobin 44 per cent, erythrocytes 1 640 000, and leucocytes 930 per c mm, the child was more lively and its appetite was improved but œdema of the legs was noted. Further transfusions were followed by progressive improvement in the blood picture. Progress was interrupted by the development of an empyema from which he made a good recovery. He was sent home at the end of December with a leucocyte count of 3700 per c mm. Soon afterwards however he developed acute tonsillitis and the leucocyte count fell to 1900 (lymphocytes 96 per

cent), and despite another blood transfusion he died within a few days.

During his illness this boy received no drug except amidopyrine, and Gorter believes that it must be held responsible for the agranulocytosis.

GAS AND BACTERIAL WARFARE

IT is doubtful whether one can further the cause of peace by making the blood curdle over the preparations being made by the Great Powers for gas and bacterial warfare. This is the object of the aim of a work¹ whose terrible theme gains nothing from the somewhat uncritical and emotional approach nor from the large amount of interesting but irrelevant padding, nor are the arguments in favour of the successful use of bacteria in war convincing. At the same time some startling revelations are given of which perhaps the most interesting is of enormous imports of arsenic into Germany as a presumed object. Of the invention of gas the author puts even Macaulay's famous school to shame with the statement that the name of Dr Berthold Schwarz has been taught to "every throughout the world."

Medical Diary

Information to be included in this column should be in proper form on Tuesday, and cannot appear if it is later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street

TUESDAY, June 29th
Psychiatry 8.30 P.M. Annual General Meeting
Erich Wittkower The Influences of the Emotions on Bodily Function
